#### Opening remarks

What have we done so far?

- Compiler overview.
- Scanning and parsing.
- JavaCC, visitors and JTB
- Semantic Analysis specification, execution, attribute grammars.
- Type checking, Intermediate Representation, Intermediate code generation.
- Control flow analysis, interval analysis, structural analysis
- Data flow analogis, intra-procedural and inter-procedural constant propagation.
- Points-to analysis

#### Announcement:

Assignment 5 is out. Due in three weeks.

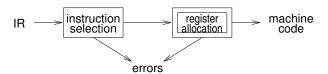

Today: Liveness analysis and register allocation.

V.Krishna Nandivada (IIT Madras)

CS6013 - Jan 2015

2/5

#### Register allocation

#### Register allocation:

- have value in a register when used
- limited resources
- can effect the instruction choices
- can move loads and stores
- optimal allocation is difficult
  - $\Rightarrow$  NP-complete for  $k \ge 1$  registers

V.Krishna Nandivada (IIT Madras) CS6013 - Jan 2015 3 / 50 V.Krishna Nandivada (IIT Madras) CS6013 - Jan 2015 4 / 5

#### Liveness analysis

#### Problem:

- IR contains an unbounded number of temporaries
- machine has bounded number of registers

#### Approach:

- temporaries with disjoint live ranges can map to same register
- if not enough registers then spill some temporaries (i.e., keep them in memory)

The compiler must perform liveness analysis for each temporary:

It is live if it holds a value that may be needed in future

V.Krishna Nandivada (IIT Madras)

CS6013 - Jan 2015

#### V.Krishna Nandivada (IIT Madras)

CS6013 - Jan 2015

 $a \leftarrow 0$ 

 $c \leftarrow c + b$ 

 $a \leftarrow b \times 2$ if a < N goto  $L_1$ 

return c

 $L_1: b \leftarrow a+1$ 

#### Liveness analysis

Gathering liveness information is a form of data flow analysis operating over the CFG:

- We will treat each statement as a different basic block.
- liveness of variables "flows" around the edges of the graph
- assignments define a variable, v:
  - def(v) = set of graph nodes that define v
  - def[n] = set of variables defined by n
- occurrences of *v* in expressions use it:
  - use(v) = set of nodes that use v
  - use[n] = set of variables used in n

#### **Definitions**

Example

- v is live on edge e if there is a directed path from SRC(e) to a use of v that does not pass through any def(v)
- v is live-in at node n if live on all of n's in-edges
- v is live-out at n if live on any of n's out-edges
- $v \in \mathit{use}[n] \Rightarrow v \text{ live-in at } n$
- v live-in at  $n \Rightarrow v$  live-out at all  $m \in pred[n]$
- v live-out at  $n, v \notin def[n] \Rightarrow v$  live-in at n

#### Liveness analysis

Define:

in[n] = variables live-in at nout[n] = variables live-out at n

Then:

$$out[n] = \bigcup_{s \in succ(n)} in[s]$$

$$succ[n] = \phi \Rightarrow out[n] = \phi$$

Note:

$$in[n] \supseteq use[n]$$
  
 $in[n] \supseteq out[n] - def[n]$ 

use[n] and def[n] are constant (independent of control flow) Now,  $v \in in[n]$  iff.  $v \in use[n]$  or  $v \in out[n] - def[n]$ Thus,  $in[n] = use[n] \cup (out[n] - def[n])$ 

V.Krishna Nandivada (IIT Madras)

CS6013 - Jan 2015

#### **Notes**

- should order computation of inner loop to follow the "flow"
- liveness flows backward along control-flow arcs, from out to in
- nodes can just as easily be basic blocks to reduce CFG size
- could do one variable at a time, from uses back to defs, noting liveness along the way

#### Iterative solution for liveness

```
N: Set of nodes of CFG:
foreach n \in N do
    in[n] \leftarrow \phi;
    out[n] \leftarrow \phi;
end
repeat
    foreach n \in Nodes do
         in'[n] \leftarrow in[n];
         out'[n] \leftarrow out[n];
         in[n] \leftarrow use[n] \cup (out[n] - def[n]);
         out[n] \leftarrow \bigcup_{s \in succ[n]} in[s];
     end
until \forall n, in'[n] = in[n] \lor out'[n] = out[n];
```

V.Krishna Nandivada (IIT Madras)

CS6013 - Jan 2015

#### Iterative solution for liveness

Complexity: for input program of size N

- < N nodes in CFG</p>
  - $\Rightarrow < N$  variables
  - $\Rightarrow N$  elements per *in/out*
  - $\Rightarrow$  O(N) time per set-union
- for loop performs constant number of set operations per node
  - $\Rightarrow$  O( $N^2$ ) time for **for** loop
- each iteration of repeat loop can only add to each set sets can contain at most every variable
  - $\Rightarrow$  sizes of all in and out sets sum to  $2N^2$ , bounding the number of iterations of the repeat loop
- $\Rightarrow$  worst-case complexity of  $O(N^4)$
- ordering can cut **repeat** loop down to 2-3 iterations
  - $\Rightarrow$  O(N) or O(N<sup>2</sup>) in practice

V.Krishna Nandivada (IIT Madras)

#### Least fixed points

There is often more than one solution for a given dataflow problem (see example).

Any solution to dataflow equations is a conservative approximation:

- v has some later use downstream from n $\Rightarrow v \in out(n)$
- but not the converse

Conservatively assuming a variable is live does not break the program; just means more registers may be needed.

Assuming a variable is dead when really live <u>will</u> break things.

Many possible solutions but we want the "smallest": the least fixpoint.

The iterative algorithm computes this least fixpoint.

V.Krishna Nandivada (IIT Madras)

CS6013 - Jan 2015

13 / 50

#### Graph coloring - a simplistic approach

```
Input: G - the interference graph, K - number of colors
repeat
   // Simplify
   repeat
       Remove a node n and all its edges from G, such that degree of n is
       less than K:
       Push n onto a stack:
   until G has no node with degree less than K:
   //\ G is either empty or all of its nodes have degree
       > K
   // Spill
   if G is not empty then
       Take one node m out of G, and mark it for spilling;
       Remove all the edges of m from G;
   end
until G is empty;
Take one node at a time from the stack and assign a non conflicting color.
```

#### Register allocation - by Graph coloring

#### Step 1:

- Select target machine instructions assuming infinite registers (temps).
- If a instruction requires a special register replace that temp with that register.
- Step 2:
  - Construct an interference graph.
  - Solve the register allocation problem by coloring the graph.
  - A graph is said to be <u>colored</u> if each each pair of neighboring nodes have different colors.

Parts of slides: sources - Andrew Myers

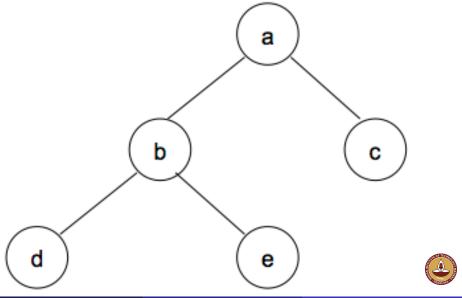

V.Krishna Nandivada (IIT Madras)

CS6013 - Jan 2015

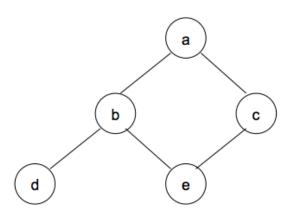

14 / 50

#### Example 1, available colors = 2

V.Krishna Nandivada(IIT Madras) CS6013 - Jan 2015 15 / 50 V.Krishna Nandivada(IIT Madras) CS6013 - Jan 2015

#### Example 2

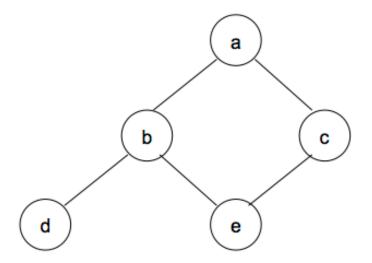

We have to spill.

V.Krishna Nandivada (IIT Madras)

CS6013 - Jan 2015

#### Example 2 (revisited)

We don't have to spill.

## Graph coloring - Kempe's heuristic

Algorithm dating back to 1879.

```
Input: G - the interference graph, K - number of colors
repeat
   repeat
       Remove a node n and all its edges from G, such that degree of n is
       less than K;
       Push n onto a stack;
```

**until** G has no node with degree less than K;

 $//\ G$  is either empty or all of its nodes have degree ≥ K

**if** *G* is not empty **then** 

Take one node m out of G.; push m onto the stack;

end

until G is empty;

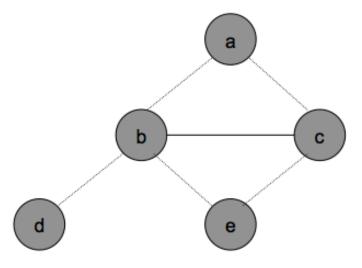

Take one node at a time from the stack and assign a non conflicting color possible, else spill).

V.Krishna Nandivada (IIT Madras)

CS6013 - Jan 2015

#### Example 3

Don't have a choice. Have to spill.

#### **Spilling**

- We need to generate extra instructions to load variables from the stack and store them back.
- The load and store may require registers again:
  - Naive approach: Keep a separate register (wasteful).
  - Rewrite the code by introducing a temporary; rerun the liveness +

(Note: the new temp has much smaller live range).

V.Krishna Nandivada (IIT Madras)

CS6013 - Jan 2015

V.Krishna Nandivada (IIT Madras)

CS6013 - Jan 2015

#### Register allocation - Linear scan

Register allocation is expensive.

- Many algorithms use heuristics for graph coloring.
- Allocation may take time quadratic in the number of live intervals.

#### Not suitable

- Online compilers need to generate code quickly. e.g. JIT compilers.
- Sacrifice efficient register allocation for compilation speed.

Linear scan register allocation - Massimiliano Poletto and Vivek Sarkar, ACM TOPLAS 1999

• Complexity linear in the number of variables (assuming the number of register is not too large).

#### Example: rewrite code

Consider: add t.1 t.2

- Suppose t2 has to be spilled, say to [sp-4].
- Invent a new temp t35, and rewrite:

- t35 has a very short live range and less likely to interfere.
- Now rerun the algo.

#### Register allocation - Chaitins

- Simplify
- Spill
- Select: assign colors to nodes
  - start with empty graph and keep adding nodes:
  - 2 if adding a non-spill node will have a color (basis for removal)
  - 3 if adding spill node and no color available (neighbors already K-colored) then mark as an actual spill; break;
  - continue to select nodes.
- Start over: if select has no actual spills then finished, otherwise
  - rewrite code: fetch spills at use, store at definition
  - 2 recalculate liveness and repeat

V.Krishna Nandivada (IIT Madras) CS6013 - Jan 2015 V.Krishna Nandivada (IIT Madras) CS6013 - Jan 2015

#### Coalescing

- Can delete a move instruction when source *s* and destination *d* do not interfere:
  - <u>coalesce</u> them into a new node whose edges are the union of those of s and d
- In principle, any pair of non-interfering nodes can be coalesced
  - ullet unfortunately, the union is more constrained and new graph may no longer be K-colorable
  - overly aggressive

V.Krishna Nandivada (IIT Madras)

CS6013 - Jan 2015

25 / 50

#### Conservative coalescing

Apply tests for coalescing that preserve colorability. Suppose a and b are candidates for coalescing into node ab. Briggs: coalesce only if ab has < K neighbors of significant degree  $\ge K$ 

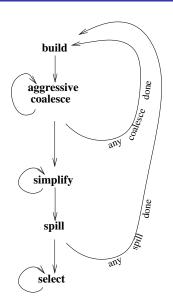

- simplify first removes all insignificant-degree neighbors
- *ab* will then be adjacent to < *K* neighbors
- simplify can then remove ab

<u>George</u>: coalesce only if all significant-degree neighbors of a already interfere with b

- simplify removes all insignificant-degree neighbors of a
- remaining significant-degree neighbors of a already interfere with b; coalescing does not increase degree of any node

#### Simplification with aggressive coalescing

V.Krishna Nandivada (IIT Madras)

CS6013 - Jan 2015

26 / 50

#### Iterated register coalescing

Interleave simplification with coalescing to eliminate most moves while guaranteeing not to introduce spills:

- <u>Build</u> interference graph G and distinguish move-related from non-move-related nodes. A move-related node is one that is either the source or destination of a move instruction.
- Simplify: remove non-move-related nodes of low degree one at a time
- Ocalesce: conservatively coalesce move-related nodes
  - remove associated move instruction
  - if resulting node is non-move-related it can now be simplified
  - repeat simplify and coalesce until only significant-degree or uncoalesced moves

V.Krishna Nandivada (IIT Madras) CS6013 - Jan 2015 27 / 50 V.Krishna Nandivada (IIT Madras) CS6013 - Jan 2015 28

#### Iterated register coalescing (cont.)

- 4. Freeze: if unable to simplify or coalesce
  - 1 look for move-related node of low-degree
  - freeze its associated moves (give up on coalescing)
  - now treat as non-move-related; resume iteration of simplify and coalesce
- 5. Spill: if no low-degree nodes
  - select candidate for spilling
  - remove to stack and continue simplifying
- 6. Select: pop stack assigning colors (with actual spills)
- 7. Start over: if select has no actual spills then finished, otherwise
  - o rewrite code: fetch spills before use, store after def
  - recalculate liveness and repeat

V.Krishna Nandivada (IIT Madras)

CS6013 - Jan 2015

29 / 50

#### Precolored nodes

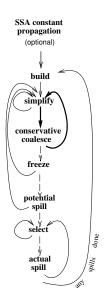

<u>Precolored nodes</u> correspond to machine registers (e.g., stack pointer, arguments, return address, return value)

- <u>select</u> and <u>coalesce</u> can give an ordinary temporary the same color as a precolored register, if they don't interfere
- e.g., argument registers can be reused inside procedures for a temporary
- simplify, freeze and spill cannot be performed on them
- also, precolored nodes interfere with other precolored nodes

So, treat precolored nodes as having infinite degree
This also avoids needing to store large adjacency lists for precolored nodes; coalescing can use the George criterion

#### Iterated register coalescing

V.Krishna Nandivada (IIT Madras)

CS6013 - Jan 2015

30 / 5

#### Temporary copies of machine registers

Since precolored nodes don't spill, their live ranges must be kept short:

- use move instructions
- move callee-save registers to fresh temporaries on procedure entry, and back on exit, spilling between as necessary
- <u>register pressure</u> will spill the fresh temporaries as necessary, otherwise they can be coalesced with their precolored counterpart and the moves deleted

V.Krishna Nandivada (IIT Madras) CS6013 - Jan 2015 31 / 50 V.Krishna Nandivada (IIT Madras) CS6013 - Jan 2015 32

#### Criteria for spilling

During register allocation, we identify that one of the live ranges from a given set, has to be spilled. Criteria?

- Random! Adv? Disadv?
- One with maximum degree
- One that has the longest life
- One with the shortest life (take advantage of the cache).
- One with least cost.
  - Cost = Dynamic (load cost + store cost)
  - How to handle loops, conditionals?
  - Cost of load, store

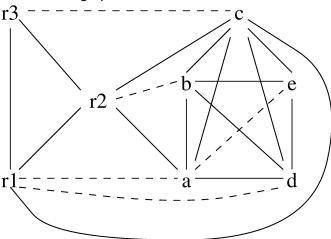

V.Krishna Nandivada (IIT Madras)

CS6013 - Jan 2015

33 / 50

#### Example (cont.)

Interference graph:

#### Example

```
enter:
    c := r3
    a := r1
    b := r2
    d := 0
    e := a
loop:
    d := d + b
    e := e - 1
    if e > 0 goto loop
    r1 := d
    r3 := c
    return [ r1, r3 live out ]
```

- Temporaries are a, b, c, d, e
- Assume target machine with K = 3 registers: r1, r2 (caller-save/argument/result), r3 (callee-save)
- The code generator has already made arrangements to save r3 explicitly by copying into temporary a and back.

V.Krishna Nandivada (IIT Madras)

CS6013 - Jan 2015

34 / 50

#### Example (cont.)

- No opportunity for <u>simplify</u> or <u>freeze</u> (all non-precolored nodes have significant degree ≥ K)
- Any <u>coalesce</u> will produce a new node adjacent to ≥ K significant-degree nodes
- Must spill based on priorities:

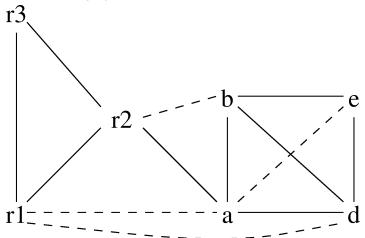

```
Node uses + defs uses + defs degree priority
        outside loop
                       inside loop
                +10\times
                                                  0.50
а
                +10\times
                                                  2.75
b
                +10\times
                                        6
                                                  0.33
С
                                                  5.50
                +10\times
d
                                                10.30
                +10\times
```

CS6013 - Jan 2015

Node c has lowest priority so spill it

Interference graph with c removed:

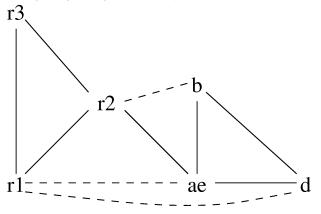

V.Krishna Nandivada (IIT Madras)

CS6013 - Jan 2015

27 / FO

## Example (cont.)

Only possibility is to  $\underline{\text{coalesce}}$  a and e: ae will have < K significant-degree neighbors (after coalescing d will be low-degree, though high-degree before)

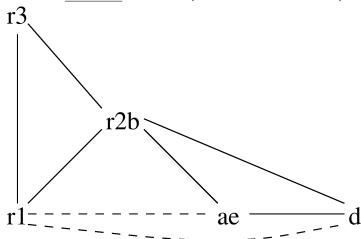

V.Krishna Nandivada (IIT Madras)

66013 - Jan 2015

20 / 50

## Example (cont.)

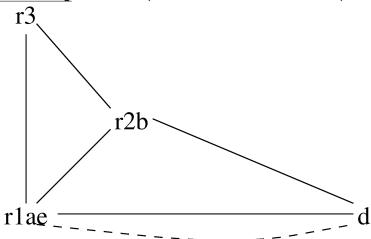

Can now coalesce b with r2 (or coalesce ae and r1):

## Example (cont.)

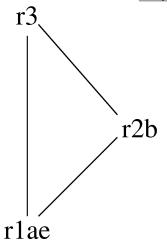

Coalescing ae and r1 (could also coalesce d with r1):

V.Krishna Nandivada(IIT Madras) CS6013 - Jan 2015 39 / 50 V.Krishna Nandivada(IIT Madras) CS6013 - Jan 2015

Cannot  $\underline{\text{coalesce}}$  rlae with d because the move is  $\underline{\text{constrained}}$ : the nodes interfere. Must simplify d:

V.Krishna Nandivada (IIT Madras)

CS6013 - Jan 2015

41 / 50

## Example (cont.)

enter:

```
c1 := r3
M[c_loc] := c1
a := r1
b := r2
d := 0
e := a
loop:
d := d + b
e := e - 1
if e > 0 goto loop
r1 := d
c2 := M[c_loc]
r3 := c2
return [ r1, r3 live out ]
```

## Example (cont.)

- Graph now has only precolored nodes, so pop nodes from stack coloring along the way
  - $d \equiv r3$
  - a, b, e have colors by coalescing
  - c must spill since no color can be found for it
- Introduce new temporaries c1 and c2 for each use/def, add loads before each use and stores after each def

V.Krishna Nandivada (IIT Madras)

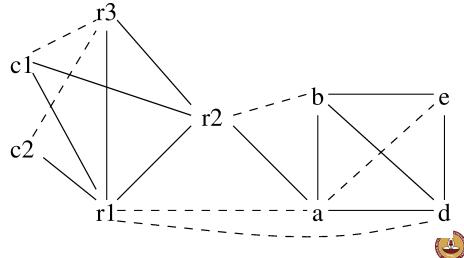

CS6013 - Jan 2015

42 / 50

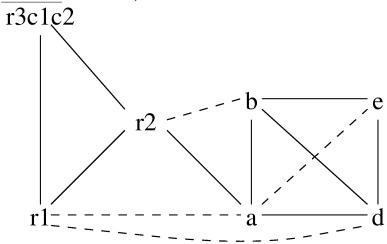

## Example (cont.)

New interference graph:

V.Krishna Nandivada (IIT Madras)

Coalesce c1 with r3, then c2 with r3:

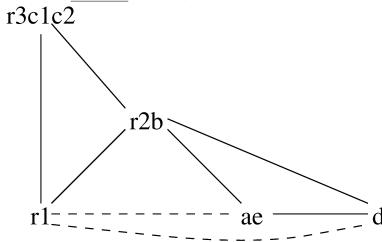

V.Krishna Nandivada (IIT Madras)

CS6013 - Jan 2015

45 / 50

## Example (cont.)

As before, coalesce a with e, then b with r2:

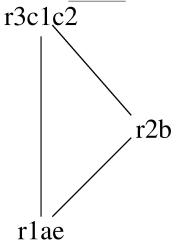

V.Krishna Nandivada (IIT Madras)

CS6013 - Jan 2015

46 / E

## Example (cont.)

As before,  $\underline{\text{coalesce}}$  ae with r1 and  $\underline{\text{simplify}}$  d:

## Example (cont.)

Pop  ${\tt d}$  from stack: select r3. All other nodes were coalesced or precolored. So, the coloring is:

- $a \equiv r1$
- $b \equiv r2$
- $c \equiv r3$
- $d \equiv r3$
- $\bullet$  e  $\equiv$  r1

 V.Krishna Nandivada (IIT Madras)
 CS6013 - Jan 2015
 47 / 50
 V.Krishna Nandivada (IIT Madras)
 CS6013 - Jan 2015
 48

Rewrite the program with this assignment:

```
enter:
    r3 := r3
    M[c_loc] := r3
    r1 := r1
    r2 := r2
    r3 := 0
    r1 := r1
loop:
    r3 := r3 + r2
    r1 := r1 - 1
    if r1 > 0 goto loop
    r1 := r3
    r3 := M[c_loc]
    r3 := r3
    return [ r1, r3 live out ]
```

V.Krishna Nandivada (IIT Madras)

CS6013 - Jan 2015

49 / 50

## Example (cont.)

• Delete moves with source and destination the same (coalesced):

```
enter:
    M[c_loc] := r3
    r3 := 0
loop:
    r2 := r3 + r2
    r1 := r1 - 1
    if r1 > 0 goto loop
    r1 := r3
    r3 := M[c_loc]
    return [ r1, r3 live out ]
```

One uncoalesced move remains

V.Krishna Nandivada (IIT Madras)

CS6013 - Jan 2015

E0 / E0
