

Signature Schemes

Chester Rebeiro
IIT Madras

Recall : MACs

MACs allow Bob to be certain that

- the message has originated from Alice
- the message was not tampered during communication

MAC cannot

- prevent Bob from creating forgeries (i.e., messages in the name of Alice)
- cannot prove Authenticity to someone without sharing the secret key K

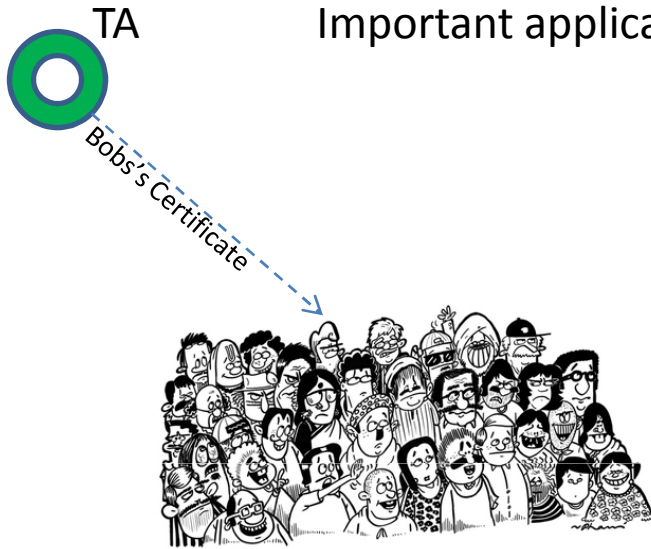

Digital Signatures solve both these problems

Digital Signatures

- A token sent along with the message that achieves
 - Authentication
 - Non-repudiation
 - Integrity
- Based on public key cryptography

Public key Certificates

Important application of digital signatures

```
Bob's Certificate{  
  Bob's public key in plaintext  
  Signature of the certifying authority  
  other information  
}
```

To communicate with Bob, Alice gets his public key from a trusted authority (TA)
A trusted authority could be a Government agency, Verisign, etc.

A signature from the TA, ensures that the public key is authentic.

Digital Signature

Alice

Everyone Else

Signing Function

$$y = \text{sig}_a(x)$$

Input : Message (x) and Alice's private key

Output: Digital Signature of Message

Verifying Function

$$\text{ver}_b(x, y)$$

Input : digital signature, message

Output : true or false

true if signature valid
false otherwise

Digital Signatures (Formally)

Definition : A *signature scheme* is a five-tuple $(\mathcal{P}, \mathcal{A}, \mathcal{K}, \mathcal{S}, \mathcal{V})$, where the following conditions are satisfied:

1. \mathcal{P} is a finite set of possible *messages*
2. \mathcal{A} is a finite set of possible *signatures*
3. \mathcal{K} , the *keyspace*, is a finite set of possible *keys*
4. For each $K \in \mathcal{K}$, there is a *signing algorithm* $\mathbf{sig}_K \in \mathcal{S}$ and a corresponding *verification algorithm* $\mathbf{ver}_K \in \mathcal{V}$. Each $\mathbf{sig}_K : \mathcal{P} \rightarrow \mathcal{A}$ and $\mathbf{ver}_K : \mathcal{P} \times \mathcal{A} \rightarrow \{true, false\}$ are functions such that the following equation is satisfied for every message $x \in \mathcal{P}$ and for every signature $y \in \mathcal{A}$:

$$\mathbf{ver}_K(x, y) = \begin{cases} true & \text{if } y = \mathbf{sig}_K(x) \\ false & \text{if } y \neq \mathbf{sig}_K(x). \end{cases}$$

A pair (x, y) with $x \in \mathcal{P}$ and $y \in \mathcal{A}$ is called a *signed message*.

Forgery

Mallory

Everyone Else

If Mallory can create a valid digital signature such that $ver_K(x, y) = TRUE$ for a message not previously signed by Alice, then the pair (x, y) forms a forgery

Security Models for Digital Signatures

Assumptions

Goals of Attacker

- **Total break:**
Mallory can determine Alice's private key
(therefore can generate any number of signed messages)
- **Selective forgery:**
Given a message x , Mallory can determine y , such
that (x, y) is a valid signature from Alice
- **Existential forgery:**
Mallory is able to create y for some x , such that
 (x, y) is a valid signature from Alice

Security Models for Digital Signatures

Assumptions

Goals of Attacker

- **Key-only attack :**

Mallory only has Alice's public key
(i.e. only has access to the verification function, *ver*)

- **Known-message attack :**

Mallory only has a list of messages signed by Alice
 $(x_1, y_1), (x_2, y_2), (x_3, y_3), (x_4, y_4), \dots$

- **Chosen-message attack :**

Mallory chooses messages x_1, x_2, x_3, \dots and tricks Alice into providing the corresponding signatures y_1, y_2, y_3 (resp.)

Weak

Strong

First Attempt making a digital signature (using RSA)

b, n public
 a, p, q private
 $n = pq; a \equiv b-1 \pmod{\phi(n)}$

```
sig(x){  
   $y \equiv x^a \pmod n$   
  return (x, y)  
}
```

(x, y)

```
ver(x, y){  
  if ( $x \equiv y^b \pmod n$ ) return TRUE  
  else return FALSE  
}
```

x is the message here
and (x, y) the signature

A Forgery for the RSA signature (First Forgery)

b, n public
 a, p, q private
 $n = pq; a \equiv b-1 \pmod{\phi(n)}$

```
sig(x){  
   $y \equiv x^a \pmod n$   
  return (x, y)  
}
```

(x, y)

```
verK(x, y){  
  if ( $x \equiv y^b \pmod n$ ) return TRUE  
  else return FALSE  
}
```

```
forgery(){  
  select a random  $y$   
  compute  $x \equiv y^b \pmod n$   
  return (x, y)  
}
```

Key only, existential forgery

Second Forgery

Suppose Alice creates signatures of two messages x_1 and x_2

$$y_1 = \text{sig}(x_1) \rightarrow y_1 \equiv x_1^a \pmod{n} \quad (x_1, y_1)$$

$$y_2 = \text{sig}(x_2) \rightarrow y_2 \equiv x_2^a \pmod{n} \quad (x_2, y_2)$$

Mallory can use the **multiplicative property of RSA** to create a forgery

$(x_1 x_2 \pmod{n}, y_1 y_2 \pmod{n})$ is a forgery

$$y_1 y_2 \equiv x_1^a x_2^a \pmod{n}$$

Known message, existential forgery

RSA Digital Signatures

Incorporate a hash function in the scheme to prevent forgery

b, n public
 a, p, q private

```
sig(x){  
  z = h(x)  
  y ≡ za mod n  
  return (x, y)  
}
```

(x, y)

```
verK(x, y){  
  z = h(x)  
  if (z ≡ yb mod n) return TRUE  
  else return FALSE  
}
```

x is the message here, (x, y) the signature
and h is a hash function

How does the hash function help?

Preventing the First Forgery

```
forger() {  
  select a random  $y$   
  compute  $z' \equiv y^b \pmod n$   
  compute 1st preimage:  $x$  st.  $z' = h(x)$   
  return  $(x, y)$   
}
```

Forgery becomes equivalent to the first preimage attack on the hash function

How does the hash function help?

Preventing the Second Forgery

$(x_1 x_2 \bmod n, y_1 y_2 \bmod n)$ is difficult

$$y_1 y_2 \equiv h(x_1)^a h(x_2)^a \bmod n$$

$$\not\equiv x_1^a x_2^a \bmod n$$

creating such a forgery is unlikely

How does the hash function help?

Another Forgery prevented

```
forger( $x, y$ ) {  
  compute  $h(x)$   
  compute  $\Pi^{nd}$  preimage: find  $x'$  s.t.  $h(x) = h(x')$  and  $x \neq x'$   
  return  $(x', y)$   
}
```

Given a valid signature (x, y) find (x', y)

creating such a forgery is equivalent to solving the 2nd preimage problem of the hash function

ElGamal Signature Scheme

- 1985
- Variant adopted by NIST as the DSA
(DSA: standard for digital signature algorithm)
- Based on the difficulty of the discrete log problem

ElGamal Signing

Initialization

Choose a large prime p
Let $\alpha \in Z_p^*$ be a primitive element
Choose a ($0 < a \leq p-1$)
Compute $\beta \equiv \alpha^a \pmod{p}$

Public Parameters : p, α, β
Private key : a

Signing Message x

```
sig(x){  
  select a secret random  $k$  s.t.  $\gcd(k, p-1) = 1$   
   $\gamma \equiv \alpha^k \pmod{p}$   
   $\delta \equiv (x - a\gamma)k^{-1} \pmod{p-1}$   
   $y = (\gamma, \delta)$   
  return  $(x, y)$   
}
```

The use of a random secret k for every signature makes ElGamal non-deterministic

ElGamal Verifying

Initialization

Choose a large prime p
Let $\alpha \in Z_p^*$ be a primitive element
Choose a ($0 < a \leq p-1$)
Compute $\beta \equiv \alpha^a \pmod{p}$

Public Parameters : p, α, β
Private key : a

Verifying Signature (x,y)

```
ver(x, (γ, δ)) {  
    compute  $t_1 \equiv \alpha^x \pmod{p}$   
    compute  $t_2 \equiv \beta^\gamma \gamma^\delta \pmod{p}$   
    if ( $t_1 = t_2$ )  
        return TRUE  
    else  
        return FALSE  
}
```

ElGamal Correctness

Signing Message x

```

sig(x){
  select a secret random  $k$ 
   $\gamma \equiv \alpha^k \pmod p$ 
   $\delta \equiv (x - a\gamma)k^{-1} \pmod{p-1}$ 
   $y = (\gamma, \delta)$ 
  return  $(x, y)$ 
}
    
```

Initialization

```

Choose a large prime  $p$ 
Let  $\alpha \in Z_p^*$  be a primitive element
Choose  $a$  ( $0 < a \leq p-1$ )
Compute  $\beta \equiv \alpha^a \pmod p$ 

Public Parameters :  $p, \alpha, \beta$ 
Private key :  $a$ 
    
```

Verifying Signature (x, y)

```

ver( $x, (\gamma, \delta)$ ){
  compute  $t_1 \equiv \alpha^x \pmod p$ 
  compute  $t_2 \equiv \beta^\gamma \gamma^\delta \pmod p$ 
  if  $(t_1 = t_2)$  return TRUE
  else return FALSE
}
    
```

correctness

First note that

$$a\gamma + k\delta \equiv x \pmod{p-1}$$

$$\begin{aligned}
 t_2 &\equiv \beta^\gamma \gamma^\delta \pmod p & t_1 &\equiv \alpha^x \pmod p \\
 &\equiv (\alpha^a)^\gamma + (\alpha^k)^\delta \pmod p \\
 &\equiv \alpha^{a\gamma+k\delta} \pmod p \\
 &\equiv \alpha^x \pmod p
 \end{aligned}$$

if the signature is valid, $t_1 = t_2$

Example

Signature of message $x = 100$

$$\begin{aligned}k &= 213 \text{ (chosen randomly)} \\k^{-1} \bmod p-1 &= 431 \\ \gamma &= \alpha^k \bmod p \\ &= 2^{213} \bmod 467 \\ &= 29 \\ \delta &= (x - a\gamma)k^{-1} \bmod p-1 \\ &= (100 - 2 \cdot 29)431 \bmod 466 \\ &= 51\end{aligned}$$

$$\begin{aligned}p &= 467 \\ \alpha &= 2 \\ a &= 127 \\ \beta &\equiv \alpha^a \bmod p \\ &= 2^{127} \bmod 467 \\ &= 132\end{aligned}$$

Verifying

$$\begin{aligned}\beta^\gamma \gamma^\delta \bmod p &= 132^{29} 29^{51} \bmod 467 = 189 \\ \alpha^x \bmod p &= 2^{100} \bmod 467 = 189 \\ \text{TRUE}\end{aligned}$$

Security of ElGamal Signature Scheme (against Selective forgery)

Given an x , Mallory needs to find (γ, δ) such that $ver(x, (\gamma, \delta)) = TRUE$

Attempt 1

Choose a value for γ , then try to compute δ s.t. $\beta^\gamma \gamma^\delta \equiv \alpha^x \pmod{p}$
 $\delta = \log_\gamma \alpha^x \beta^{-\gamma}$

This is the intractable discrete log problem

Attempt 2

Choose a value for δ , then try to compute γ s.t. $\beta^\gamma \gamma^\delta \equiv \alpha^x \pmod{p}$

This is not related to the discrete log problem. There is no known solution for this.

Attempt 3

Choose value for γ and δ simultaneously, s.t. $\beta^\gamma \gamma^\delta \equiv \alpha^x \pmod{p}$

No way known.

Security of ElGamal Signature Scheme (against Existential forgery)

Mallory needs to find an $(x, (\gamma, \delta))$ such that $ver(x, (\gamma, \delta)) = TRUE$

The one-parameter forgery

forgery

choose some i $(0 \leq i \leq p-2)$.
 form $\gamma \equiv \alpha^i \beta \pmod{p}$
 $\delta \equiv -\gamma \pmod{p-1}$
 $x \equiv i\delta \pmod{p-1}$.
 then, $ver(x, (\gamma, \delta)) = TRUE$
 $\alpha^x \equiv \beta^\gamma \gamma^\delta \pmod{p}$

proof

$RHS \equiv \beta^\gamma (\alpha^i \beta)^\delta \pmod{p}$
 $\equiv \beta^{\gamma+\delta} \alpha^{i\delta} \pmod{p}$
 $\equiv \alpha^{a\gamma+a\delta} \alpha^{i\delta} \pmod{p}$
 $\equiv \alpha^{a\gamma-a\gamma+i\delta} \pmod{p}$
 $\equiv \alpha^{i\delta} \pmod{p}$
 $\equiv \alpha^x \pmod{p} = LHS$

Security of ElGamal Signature Scheme (*against Existential forgery*)

Mallory needs to find an $(x, (\gamma, \delta))$ such that $ver(x, (\gamma, \delta)) = TRUE$

The two-parameter forgery

forgery

choose some i, j ($0 \leq i, j \leq p-2$; $\gcd(j, p-1) = 1$)

form $\gamma \equiv \alpha^i \beta^j \pmod{p}$

$\delta \equiv -\gamma^{-1} \pmod{p-1}$

$x \equiv \gamma j^{-1} \pmod{p-1}$.

then, $ver(x, (\gamma, \delta)) = TRUE$

Prevent Existential Forgeries by hashing the message

Improper use of ElGamal's Signature Scheme

1. What if k is not a secret?

if $\gcd(\gamma, p-1) = 1$ then

secret a can be computed as follows

$$a = (x - k\delta)\gamma^{-1} \bmod (p-1).$$

```
sig(x){  
  select a secret random  $k$   
   $\gamma \equiv \alpha^k \bmod p$   
   $\delta \equiv (x - a\gamma)k^{-1} \bmod p-1$   
   $y = (\gamma, \delta)$   
  return  $(x, y)$   
}
```

The secret key 'a' is retrieved and Mallory can create many forgeries

Improper use of ElGamal's Signature Scheme

2. What if k is reused?

Lets say we have two different messages x_1 and x_2 signed with the same k

The signatures are (γ, δ_1) and (γ, δ_2) then,

$$\beta^\gamma \gamma^{\delta_1} \equiv \alpha^{x_1} \pmod{p}$$

$$\beta^\gamma \gamma^{\delta_2} \equiv \alpha^{x_2} \pmod{p}.$$

dividing

$$\alpha^{x_1 - x_2} \equiv \gamma^{\delta_1 - \delta_2} \pmod{p}.$$

Representing in terms of α

$$\alpha^{x_1 - x_2} \equiv \alpha^{k(\delta_1 - \delta_2)} \pmod{p},$$

=>

$$x_1 - x_2 \equiv k(\delta_1 - \delta_2) \pmod{p - 1}.$$

```
sig(x){
  select a secret random k
   $\gamma \equiv \alpha^k \pmod{p}$ 
   $\delta \equiv (x - a\gamma)k^{-1} \pmod{p - 1}$ 
   $y = (\gamma, \delta)$ 
  return (x, y)
}
```

Improper use of ElGamal's Signature Scheme

$$x_1 - x_2 \equiv k(\delta_1 - \delta_2) \pmod{p-1}.$$

Now let $d = \gcd(\delta_1 - \delta_2, p - 1)$. Since $d \mid (p - 1)$ and $d \mid (\delta_1 - \delta_2)$, it follows that $d \mid (x_1 - x_2)$. Define

$$x' = \frac{x_1 - x_2}{d} \quad \delta' = \frac{\delta_1 - \delta_2}{d} \quad p' = \frac{p - 1}{d}.$$

Then the congruence becomes:

$$x' \equiv k\delta' \pmod{p'}.$$

Since $\gcd(\delta', p') = 1$, we can compute

$$\epsilon = (\delta')^{-1} \pmod{p'}.$$

Then value of k is determined modulo p' to be

$$k \equiv x'\epsilon \pmod{p'}.$$

This yields d candidate values for k :

$$k \equiv x'\epsilon + ip' \pmod{p-1}$$

for some i , $0 \leq i \leq d - 1$. Of these d candidate values, the (unique) correct one can be determined by testing the condition

$$\gamma \equiv \alpha^k \pmod{p}.$$

ElGamal Signature Length

- Generally p is a prime of length 1024 bits
- The signature comprises of (γ, δ) which is of length 2048 bits

Schnorr's Signature Scheme is a modification of the ElGamal signature scheme with signatures of length around 320 bits

DSA (Digital Signature Standard)

Initialization

Choose a large prime p (1024 bit)
Choose another prime q (160 bit) s.t. $q \mid p-1$
Find α of order q (α creates a subgroup of order q)
Choose a ($0 < a \leq q-1$)
Compute $\beta \equiv \alpha^a \pmod{p}$

Public Parameters : p, q, α, β
Private key : a

choose some α
And compute
 $\alpha^{(p-1)/q} \pmod{p}$

DSA (Signing Function)

Initialization

Choose a large prime p (1024 bit)

Choose another prime q (160 bit) s.t. $q \mid p-1$

Find α of order q (α creates a subgroup of order q)

Choose a ($0 < a \leq q-1$)

Compute $\beta \equiv \alpha^a \pmod{p}$

Public Parameters : p, q, α, β

Private key : a

Signing Message x

```
sig(x){  
  select a secret random  $k$  s.t.  $\gcd(k, q) = 1$   
   $\gamma \equiv (\alpha^k \pmod{p}) \pmod{q}$   
   $\delta \equiv (SHA(x) + a\gamma)k^{-1} \pmod{q}$   
   $y = (\gamma, \delta)$   
  return  $(x, y)$   
}
```

The use of a random secret k for every signature makes ElGamal non-deterministic

DSA (Verifying Function)

Initialization

Choose a large prime p (1024 bit)
Choose another prime q (160 bit) *s.t.* $q \mid p-1$
Find α of order q (α creates a subgroup of order q)
Choose a ($0 < a \leq q-1$)
Compute $\beta \equiv \alpha^a \pmod{p}$

Public Parameters : p, q, α, β
Private key : a

Signing Message x

```
sig(x){  
  select a secret random  $k$  s.t.  $\gcd(k, q) = 1$   
   $\gamma \equiv (\alpha^k \pmod{p}) \pmod{q}$   
   $\delta \equiv (SHA(x) + a\gamma)k^{-1} \pmod{q}$   
   $y = (\gamma, \delta)$   
  return  $(x, y)$   
}
```

Verifying Signature

```
ver(x, ( $\gamma, \delta$ )){  
  compute  $w \equiv \delta^{-1} \pmod{q}$   
  compute  $t_1 \equiv w \cdot SHA(x) \pmod{q}$   
  compute  $t_2 \equiv w \cdot \gamma \pmod{q}$   
  compute  $v \equiv (\alpha^{t_1} \cdot \beta^{t_2} \pmod{p}) \pmod{q}$   
  if  $(v \equiv \gamma \pmod{q})$  return TRUE  
  else return FALSE  
}
```

DSA (Correctness)

Initialization

Public Parameters : p, q, α, β ($\beta \equiv \alpha^a \pmod{p}$)

Private key : a

Verifying Signature

Signing Message x

```
sig(x){  
  select a secret random  $k$  s.t.  $\gcd(k, q) = 1$   
   $\gamma \equiv (\alpha^k \pmod{p}) \pmod{q}$   
   $\delta \equiv (SHA(x) + a\gamma)k^{-1} \pmod{q}$   
   $y = (\gamma, \delta)$   
  return  $(x, y)$   
}
```

```
ver(x, ( $\gamma, \delta$ )){  
  compute  $w \equiv \delta^{-1} \pmod{q}$   
  compute  $t_1 \equiv w \cdot SHA(x) \pmod{q}$   
  compute  $t_2 \equiv w \cdot \gamma \pmod{q}$   
  compute  $v \equiv (\alpha^{t_1} \cdot \beta^{t_2} \pmod{p}) \pmod{q}$   
  if  $(v \equiv \gamma \pmod{q})$  return TRUE  
  else return FALSE  
}
```

$$\delta \equiv (SHA(x) + a\gamma)k^{-1} \pmod{q}$$

$$k \equiv (SHA(x) + a\gamma)\delta^{-1} \pmod{q}$$

$$= (wSHA(x) + wa\gamma) \pmod{q}$$

$$k \equiv (t_1 + at_2) \pmod{q}$$

$$\alpha^k \equiv \alpha^{(t_1 + at_2) \pmod{q}} \pmod{p}$$

$$\alpha^k \equiv \alpha^{t_1} \beta^{t_2} \pmod{p}$$

Take mod q on both sides

$$\gamma \equiv (\alpha^{t_1} \beta^{t_2} \pmod{p}) \pmod{q}$$

Security of DSA

- There are two ways to attack the DSA (attempt to recover the secret a)
 - Target the large cyclic group Z_p
 - Target the smaller group Z_q

Could you techniques such as Index Calculus. For a 1024 bit p , this method offers security of 80 bits

Cannot apply Index Calculus relies on Pollard rho for solving the discrete log, For 160 bit q , this offers security of 80 bits

Security of DSA

- There are two ways to attack the DSA (attempt to recover the secret a)
 - Target the large cyclic group Z_p
 - Target the smaller group Z_q

Could you techniques such as Index Calculus. For a 1024 bit p , this method offers security of 80 bits

Cannot apply Index Calculus relies on Pollard rho for solving the discrete log, For 160 bit q , this offers security of 80 bits

Thus the size of p dictates the size of q .

p	q	Signature
1024	160	320
2048	224	448
3072	256	512

Schnorr Signature Scheme

(uses a hash function to get smaller signatures)

Initialization

Choose a large prime p (of size 1024 bits)
Choose a smaller prime q (of size 160 bits) and $q \mid (p-1)$
Let $\alpha_0 \in Z_p^*$ be a primitive element
then $\alpha = \alpha_0^{(p-1)/q} \bmod p$ is the q^{th} root of 1 mod p
Choose a randomly from $(0 \leq a < q)$
Compute $\beta = \alpha^a \bmod q$
Private: a
Private: α, β, p, q

Signing Message x

```
sig(x){  
  select a secret random  $k$  s.t.  $1 \leq k \leq q-1$ .  
   $\gamma = h(x \parallel \alpha^k \bmod p)$   
   $\delta = k + a\gamma \bmod p$   
   $y = (\gamma, \delta)$   
  return  $(x, y)$   
}
```

Verifying Signature (x, y)

```
ver(x, (γ, δ)){  
  compute  $t_1 \equiv h(x \parallel \alpha^\delta \beta^{-\gamma} \bmod p)$   
  if  $(t_1 = \gamma)$  return TRUE  
  else return FALSE  
}
```
