# Block Ciphers 

## Chester Rebeiro <br> IIT Madras

STINSON : chapters 3

## Block Cipher

Encryption key is the same as the decryption key ( $\mathrm{K}_{\mathrm{E}}=\mathrm{K}_{\mathrm{D}}$ )

## Block Cipher : Encryption

- A block cipher encryption algorithm encrypts n bits of plaintext at a time
- May need to pad the plaintext if necessary
- $y=e_{k}(x)$

## Block Cipher : Decryption

- A block cipher decryption algorithm recovers the plaintext from the ciphertext.
- $x=d_{k}(y)$

## Inside the Block Cipher (an iterative cipher)

- Each round has the same endomorphic cryptosystem, which takes a key and produces an intermediate ouput
- Size of the key is huge... much larger than the block size.

## Inside the Block Cipher (the key schedule)

Secret Key

Ciphertext Block

- A single secret key of fixed size used to generate 'round keys' for each round

## Inside the Round Function

- Add Round key :

Mixing operation between the round input and the round key. typically, an ex-or operation

- Confusion layer :

Makes the relationship between round input and output complex.

- Diffusion layer:
dissipate the round input.
Avalanche effect : A single bit change in the round input should cause huge changes in the output.
Makes it difficult for the attacker to pick out some bits over the others (think Hill cipher)

## Achieving Confusion and Diffusion (Substitution-Permutation Networks)

- Confusion achieved by small substitution functions
- Diffusion achieved by diffusion functions
- Permutations
- Linear Transformations

## Diffusion with Permutations

- Spreads the output of one s-box to other s-boxes
- Thus causing a diffusion.
- A single bit change in one input (before S1 for instance) affects four inputs of the next round
- Bit wise permutations efficient in hardware but not in software implementations

## Permutation Layer Types ${ }^{0123}$

- straight ( $24 \times 24$ )
$0^{\text {th }}$ bit of input goes to $1^{\text {st }}$ bit of output
$1^{\text {st }}$ bit of input goes
to $15^{\text {th }}$ bit of output

| 01 | 15 | 02 | 13 | 06 | 17 | 03 | 19 | 09 | 04 | 21 | 11 |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| 14 | 05 | 12 | 16 | 18 | 07 | 24 | 10 | 23 | 08 | 22 | 20 |

- expansion (12x24)

| 01 | 03 | 02 | 01 | 06 | 17 | 03 | 07 | 09 | 04 | 09 | 11 |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| 02 | 05 | 12 | 04 | 06 | 07 | 12 | 10 | 11 | 08 | 10 | 08 |

- compression ( $24 \times 12$ )

| 01 | 15 | 02 | 13 | 06 | 17 | 03 | 19 | 09 | 04 | 21 | 11 |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |

## Permutation Layer (more variants)

- Common permutation operations which are used in block ciphers
- circular shift
- Circular shift input N bits to right (or left)
- swap
- Special case of circular shift with shift = N/2

## Diffusion with Linear Transformation

- Linear combination of the inputs (can be done byte wise; more software friendly, as no bit manipulations needed)

$$
\left[\begin{array}{llll}
2 & 3 & 1 & 1 \\
1 & 2 & 3 & 1 \\
1 & 1 & 2 & 3 \\
3 & 1 & 1 & 2
\end{array}\right] *\left[\begin{array}{l}
x_{1} \\
x_{2} \\
x_{3} \\
x_{4}
\end{array}\right]=\left[\begin{array}{l}
y_{1} \\
y_{2} \\
y_{3} \\
y_{4}
\end{array}\right] \quad \begin{aligned}
& \text { Example. } \\
& \text { The AES mix column operation }
\end{aligned}
$$

- How to choose the linear transformation in the Permutation layer?
- Need to have good diffusion properties
- Should have Maximum Branch Number

$$
\text { BranchNumber }=\operatorname{MIN}_{(a \neq 0)}(W(a)+W(F(a))
$$

## Branch Number

$$
\text { BranchNumber }=\operatorname{MIN}_{(a \neq 0)}(W(a)+W(F(a))
$$

- Byte Vector : Number of non-zero input bytes
- W(a) : Byte vector of input (i.e. non-zero bytes in a)
- W(F(a)) : Byte vector of output (i.e. non-zero bytes in the output)

$$
\left[\begin{array}{llll}
2 & 3 & 1 & 1 \\
1 & 2 & 3 & 1 \\
1 & 1 & 2 & 3 \\
3 & 1 & 1 & 2
\end{array}\right] *\left[\begin{array}{l}
x_{1} \\
x_{2} \\
x_{3} \\
x_{4}
\end{array}\right]=\left[\begin{array}{l}
y_{1} \\
y_{2} \\
y_{3} \\
y_{4}
\end{array}\right] \quad \begin{aligned}
& \text { Example. } \\
& \text { The AES mix column operation }
\end{aligned}
$$

- example: AES mix column matrix has a branch number of 5
- 1 non-zero byte in input causes all 4 bytes of output to change
- 2 non-zero byte in input causes at-least 3 bytes of output to change (and so on...)

## Substitution Layer (Sbox)

- A lot of the block cipher's security rests with this.
- Replaces its input with another

| $z$ | 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | $A$ | $B$ | $C$ | $D$ | $E$ | $F$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $\pi_{S}(z)$ | $E$ | 4 | $D$ | 1 | 2 | $F$ | $B$ | 8 | 3 | $A$ | 6 | $C$ | 5 | 9 | 0 | 7 |

- As with the permutation layer, can be straight sbox (mxm)
expansion sbox ( $m \times n, m<n$ )
compression sbox (mxn, m>n)

## Sboxes

- In an s-box each output bit can be represented as a function of its input bits

$$
\begin{aligned}
& y_{1}=f_{1}\left(x_{1}, x_{2}, x_{3}, \cdots, x_{m}\right) \\
& y_{2}=f_{2}\left(x_{1}, x_{2}, x_{3}, \cdots, x_{m}\right) \\
& y_{3}=f_{3}\left(x_{1}, x_{2}, x_{3}, \cdots, x_{m}\right) \\
& \vdots \\
& \quad \vdots \quad \vdots \quad \vdots \\
& y_{n}= \\
& f_{n}\left(x_{1}, x_{2}, x_{3}, \cdots, x_{m}\right)
\end{aligned}
$$

The functions have to be non-linear. Linear functions are easily reversed.

## S-boxes are Non-linear transformations

$$
\begin{aligned}
& y_{1}=a_{1} x_{1} \oplus a_{2} x_{2} \oplus a_{3} x_{3} \oplus \cdots \oplus a_{m} x_{m} \\
& y_{2}=a_{1} x_{1} \oplus a_{2} x_{2} \oplus a_{3} x_{3} \oplus \cdots \oplus a_{m} x_{m} \\
& \cdots=\cdots \\
& y_{n}=a_{1} x_{1} \oplus a_{2} x_{2} \oplus a_{3} x_{3} \oplus \cdots \oplus a_{m} x_{m}
\end{aligned}
$$

where $a_{1}, a_{2}, \cdots a_{m} \in\{0,1\}$

- Non-linear s-boxes do not have equations like the above.
- Instead they non-linear equations as follows

$$
y_{1}=a_{1} x_{1} \oplus a_{2} x_{1} x_{2} \oplus a_{3} x_{1} x_{5} x_{2} \cdots
$$

## example : Simplified DES SBox

Non-linear equations for SO

$$
\begin{aligned}
q & =a b c d+a b+a c+b+d \\
r & =a b c d+a b d+a b+a c+a d+a+c+1
\end{aligned}
$$

## Why Non-linearity?

- We want to make it difficult for reversing an s-box: i.e. determine x from y

- Solving linear equations can be done in polynomial time
- Solving non-linear equation is NP hard
- Note the difference with the permutation layer, which is a linear layer. The main purpose of the permutation layer is to provide diffusion and not to confuse!

## ex-or (An Important Operation)

## - Used considerably for key addition

- Ex-or $(\oplus)$ is a binary operation, which results in 1 when both inputs have a different value. Otherwise 0
- Application of Ex-or in ciphers
- During Encryption : $p \oplus k=c$
- During decryption : $c \oplus k=p$

The same operation can be used during encryption as well as decryption

## Block Cipher Design Techniques

- Substitution-Permutation Networks (SPN)
- AES, PRESENT, SHARK
- Feistel Ciphers
- DES, CLEFIA, SERPENT, RC5, ... and many more

## A Four Round SPN Block Cinher

- An SPN block cipher contains repeating rounds of
- Key addition
- Add randomization
- Substitution
- A non-linear layer
- Diffusion
- A linear layer for spreading
- The repeating randomization, nonlinear and linear layers makes it difficult to cryptanalyse
- Used in ciphers such as
- AES (Advanced Encryption Standard)
- PRESENT (The Light weight block cipher standard)

SPN: Substitution Permutation Network

## Diffusion in the SPN

- A single bit of plaintext gets diffused to all bits of the ciphertext.
- If a single bit in the plaintext is flipped
- Each bit of the ciphertext will flip with probability $1 / 2$
- In other words, half the bits of the ciphertext will flip.
- If, even a single bit of the key is wrong, half the bits of the ciphertext is flipped

## Decryption

## - Is the reverse process

- Start with the ciphertext and do all operations in the reverse order
- The round keys are applied in the reverse order
- Permutation layer should be inverse
- Substitution (S-boxes) should be inverse
- This also means that the inverse of the s-box should exist

## Feistel Ciphers

- A popular technique for designing block ciphers
- Examples: DES, RC5, CLEFIA,
- Does not require invertible substitution and permutation layers

Encryption

$$
\begin{aligned}
L_{i} & =R_{i} \\
R_{i} & =L_{i} \oplus F\left(R_{i-1}, K_{i-1}\right)
\end{aligned}
$$

Decryption

$$
R_{i-1}=L_{i}
$$

$$
L_{i-1}=R_{i} \oplus F\left(L_{i-1}, K_{i-1}\right)
$$

## What does F contain?

- contains : key mixing, substitution, permutation
- A single round of DES

the sboxes (S1 to S 8 ) are $6 \times 4 \ldots$ they are not invertible

## 3 round Fiestel cipher

- Iterative

## Linear Cryptanalysis

## Non-linearity in S-boxes

- In the 1970s, cryptographers took a lot of care in designing s-boxes
- each output bit of the s-box was the output of a complex non-linear function of the input bits. Like this

$$
y_{1}=a_{1} x_{1} \oplus a_{2} x_{1} x_{2} \oplus a_{3} x_{1} x_{5} x_{2} \cdots
$$

- also, the value of each output bit was un-biased
i.e. $\operatorname{Pr}\left[y_{i}=0\right]=\operatorname{Pr}\left[y_{i}=1\right]=1 / 2 \quad$ for $1 \leq i \leq n$

This meant that it was difficult to infer anything about $x$ from an output bit

## Linear Approximations

- they overlooked about linear combinations of the s-box output which turned out to be biased...such as

$$
\begin{array}{ll}
\operatorname{Pr}\left[y_{1} \oplus x_{1} \oplus x_{5} \oplus x_{7}=0\right] \ll 1 / 2 \text { or } \quad \text { low probability of occurrence } \\
\operatorname{Pr}\left[y_{1} \oplus x_{1} \oplus x_{5} \oplus x_{7}=1\right] \gg 1 / 2
\end{array} \text {,high probability of occurrence }
$$

- This bias was exploited by Mitsuru Matsui in 1993 to attack DES. The attack was known as linear cryptanalysis
- it is a known plaintext attack
- required $2^{43}$ known plaintext-ciphertext pairs to break DES

## Bias

## (A measure of deviation from uniform randomness)

- Consider $\mathbf{X}_{1}, \mathbf{X}_{2}, \ldots$ discrete independent random variables over $\{0,1\}$
- Let $\operatorname{Pr}\left[\mathbf{X}_{\mathbf{i}}=\mathbf{0}\right]=p_{i}$, thus $\operatorname{Pr}\left[\mathbf{X}_{\mathbf{i}}=1\right]=1-p_{i}$ for $\mathrm{i}=1,2,3, \ldots$.
- Due to independence, the joint probability is obtained by simply multiplying. Thus for $\mathrm{i} \neq \mathrm{j}$,

$$
\begin{array}{ll}
\operatorname{Pr}\left[\mathbf{X}_{\mathbf{i}}=0, \mathbf{X}_{\mathbf{j}}=0\right]=p_{i} p_{j} & \operatorname{Pr}\left[\mathbf{X}_{\mathbf{i}}=1, \mathbf{X}_{\mathbf{j}}=0\right]=\left(1-p_{i}\right) p_{j}, \\
\operatorname{Pr}\left[\mathbf{X}_{\mathbf{i}}=0, \mathbf{X}_{\mathbf{j}}=1\right]=p_{i}\left(1-p_{j}\right) & \operatorname{Pr}\left[\mathbf{X}_{\mathbf{i}}=1, \mathbf{X}_{\mathbf{j}}=1\right]=\left(1-p_{i}\right)\left(1-p_{j}\right) .
\end{array}
$$

- Consider discrete random variables $\mathbf{X}_{\mathbf{i}} \oplus \mathbf{X}_{\mathbf{j}}$ where $\mathrm{i} \neq \mathrm{j}$

$$
\begin{aligned}
& \mathbf{P r}\left[\mathbf{X}_{\mathbf{i}} \oplus \mathbf{X}_{\mathbf{j}}=0\right]=p_{i} p_{j}+\left(1-p_{i}\right)\left(1-p_{j}\right) \\
& \mathbf{P r}\left[\mathbf{X}_{\mathbf{i}} \oplus \mathbf{X}_{\mathbf{j}}=1\right]=p_{i}\left(1-p_{j}\right)+\left(1-p_{i}\right) p_{j} .
\end{aligned}
$$

## Bias

- Define bias of $X_{i}$ as $\epsilon_{i}=p_{i}-\frac{1}{2}$.
- Some properties of the bias

$$
\begin{aligned}
& \text { (1) }-\frac{1}{2} \leq \epsilon_{i} \leq \frac{1}{2}, \\
& \begin{array}{l}
\text { (2) } \operatorname{Pr}\left[\mathbf{X}_{\mathbf{i}}=0\right]=\frac{1}{2}+\epsilon_{i}, \\
\operatorname{Pr}\left[X_{i} \oplus X_{j}=0\right]=\operatorname{Pr}\left[X_{i}=0\right] \operatorname{Pr}\left[X_{j}=0\right]+\operatorname{Pr}\left[X_{i}=1\right] \operatorname{Pr}\left[X_{j}=1\right] \\
\\
\text { (4) }\left(\frac{1}{2}+\varepsilon_{i}\right)\left(\frac{1}{2}+\varepsilon_{j}\right)+\left(\frac{1}{2}-\varepsilon_{i}\right)\left(\frac{1}{2}-\varepsilon_{j}\right)=\left(\frac{1}{2}+2 \varepsilon_{i} \varepsilon_{j}\right)
\end{array}
\end{aligned}
$$

- If the bias is 0 then $X_{i}$ can take values of 0 or 1 with equal probability
The further the bias is from 0 (ie. close to $\pm 1 / 2$ ) then $\mathrm{X}_{\mathrm{i}}$ takes 0 with higher (or lower) probability
- The bias is therefore a measure of the randomness

## Linear Approximations of an s-box

 How to construct?$$
\begin{array}{c||c|c|c|c|c|c|c|c|c|c|c|c|c|c|c|c}
z & 0 & 1 & 2 & 3 & 4 & 5 & 6 & 7 & 8 & 9 & A & B & C & D & E & F \\
\hline \pi_{S}(z) & E & 4 & D & \mathbf{1} & 2 & F & B & 8 & 3 & A & 6 & C & 5 & 9 & 0 & 7
\end{array}
$$

| $\mathbf{X}_{\mathbf{1}}$ | $\mathbf{X}_{\mathbf{2}}$ | $\mathbf{X}_{\mathbf{3}}$ | $\mathbf{X}_{\mathbf{4}}$ | $\mathbf{Y}_{\mathbf{1}}$ | $\mathbf{Y}_{\mathbf{2}}$ | $\mathbf{Y}_{\mathbf{3}}$ | $\mathbf{Y}_{\mathbf{4}}$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 0 | 0 | 0 | 0 | 1 | 1 | 1 | 0 |
| 0 | 0 | 0 | 1 | 0 | 1 | 0 | 0 |
| 0 | 0 | 1 | 0 | 1 | 1 | 0 | 1 |
| 0 | 0 | 1 | 1 | 0 | 0 | 0 | 1 |
| 0 | 1 | 0 | 0 | 0 | 0 | 1 | 0 |
| 0 | 1 | 0 | 1 | 1 | 1 | 1 | 1 |
| 0 | 1 | 1 | 0 | 1 | 0 | 1 | 1 |
| 0 | 1 | 1 | 1 | 1 | 0 | 0 | 0 |
| 1 | 0 | 0 | 0 | 0 | 0 | 1 | 1 |
| 1 | 0 | 0 | 1 | 1 | 0 | 1 | 0 |
| 1 | 0 | 1 | 0 | 0 | 1 | 1 | 0 |
| 1 | 0 | 1 | 1 | 1 | 1 | 0 | 0 |
| 1 | 1 | 0 | 0 | 0 | 1 | 0 | 1 |
| 1 | 1 | 0 | 1 | 1 | 0 | 0 | 1 |
| 1 | 1 | 1 | 0 | 0 | 0 | 0 | 0 |
| 1 | 1 | 1 | 1 | 0 | 1 | 1 | 1 |

Represent the s-box in binary as in the following table

## Linear Approximations of an s-box

Consider a linear combination of inputs and ouputs
For example $X_{1} \oplus X_{4} \oplus Y_{2}$ and fill in the truth table

| $\mathrm{X}_{1}$ | $\mathbf{X}_{4}$ | $Y_{2}$ |  |
| :---: | :---: | :---: | :---: |
| 0 | 0 | 1 | 1 |
| 0 | 1 | 1 | 0 |
| 0 | 0 | 1 | 1 |
| 0 | 1 | 0 | 1 |
| 0 | 0 | 0 | 0 |
| 0 | 1 | 1 | 0 |
| 0 | 0 | 0 | 0 |
| 0 | 1 | 0 | 1 |
| 1 | 0 | 0 | 1 |
| 1 | 1 | 0 | 0 |
| 1 | 0 | 1 | 0 |
| 1 | 1 | 1 | 1 |
| 1 | 0 | 1 | 0 |
| 1 | 1 | 0 | 0 |
| 1 | 0 | 0 | 1 |
| 1 | 1 | 1 | 1 |

$$
\begin{aligned}
& \text { \#1s }=8 \\
& \text { \#0s }=8 \\
& p=\operatorname{Pr}\left[X_{1} \oplus X_{4} \oplus Y_{2}=0\right]=1 / 2 \\
& \varepsilon=p-\frac{1}{2}=0 \\
& \text { unbiased }
\end{aligned}
$$

## Linear Approximations of an s-box

Consider a linear combination of inputs and ouputs for example $X_{1} \oplus X_{2} \oplus X_{3} \oplus Y_{2}$ and fill in the truth table

| $\mathrm{X}_{1}$ | $\mathrm{X}_{2}$ | $\mathbf{X}_{3}$ | $Y_{2}$ |  |
| :---: | :---: | :---: | :---: | :---: |
| 0 | 0 | 0 | 1 | 1 |
| 0 | 0 | 0 | 1 | 1 |
| 0 | 0 | 1 | 1 | 0 |
| 0 | 0 | 1 | 0 | 1 |
| 0 | 1 | 0 | 0 | 1 |
| 0 | 1 | 0 | 1 | 0 |
| 0 | 1 | 1 | 0 | 0 |
| 0 | 1 | 1 | 0 | 0 |
| 1 | 0 | 0 | 0 | 1 |
| 1 | 0 | 0 | 0 | 1 |
| 1 | 0 | 1 | 1 | 1 |
| 1 | 0 | 1 | 1 | 1 |
| 1 | 1 | 0 | 1 | 1 |
| 1 | 1 | 0 | 0 | 0 |
| 1 | 1 | 1 | 0 | 1 |
| 1 | 1 | 1 | 1 | 0 |

$$
\begin{aligned}
& \text { \#1s }=10 \\
& \text { \#0s }=6 \\
& p=\operatorname{Pr}\left[X_{1} \oplus X_{2} \oplus X_{3} \oplus Y_{2}=0\right]=3 / 8 \\
& \varepsilon=p-\frac{1}{2}=-\frac{1}{8}=-0.125
\end{aligned}
$$

## Linear Approximations of an s-box

Consider another example $X_{3} \oplus X_{4} \oplus Y_{1} \oplus Y_{4}$ and fill in the truth table

| $\mathbf{X}_{\mathbf{3}}$ | $\mathbf{X}_{\mathbf{4}}$ | $\mathbf{Y}_{\mathbf{1}}$ |
| :---: | :---: | :---: |
| 0 | 0 | 1 |
| 0 | 1 | 0 |
| 1 | 0 | 1 |
| 1 | 1 | 0 |
| 0 | 0 | 0 |
| 0 | 1 | 1 |
| 1 | 0 | 1 |
| 1 | 1 | 1 |
| 0 | 0 | 0 |
| 0 | 1 | 1 |
| 1 | 0 | 0 |
| 1 | 1 | 1 |
| 0 | 0 | 0 |
| 0 | 1 | 1 |
| 1 | 0 | 0 |
| 1 | 1 | 0 |

| $\mathbf{Y}_{\mathbf{4}}$ |  |
| :---: | :---: |
| 0 | 1 |
| 0 | 1 |
| 1 | 0 |
| 1 | 1 |
| 0 | 0 |
| 1 | 1 |
| 1 | 1 |
| 0 | 1 |
| 1 | 1 |
| 0 | 1 |
| 0 | 1 |
| 0 | 1 |
| 1 | 1 |
| 1 | 1 |
| 0 | 1 |
| 1 | 1 |

$$
\begin{aligned}
& \# 1 \mathrm{~s}=14 \\
& \# 0 \mathrm{~s}=2 \\
& p=\operatorname{Pr}\left[X_{3} \oplus X_{4} \oplus Y_{1} \oplus Y_{4}=0\right]=1 / 8 \\
& \varepsilon=p-\frac{1}{2}=-\frac{3}{8}=-.375
\end{aligned}
$$

Highly biased

## Linear Approximation Tables

# $\left(\bigoplus_{i=1}^{4} a_{i} \mathbf{X}_{\mathbf{i}}\right) \oplus\left(\bigoplus_{i=1}^{4} b_{i} \mathbf{Y}_{\mathbf{i}}\right)$ 

where $a_{i} \in\{0,1\}, b_{i} \in\{0,1\}, i=1,2,3,4$.

$$
\varepsilon(a, b)=\frac{N L(a, b)-8}{16}
$$

| $X_{3} \oplus X_{4} \oplus Y_{1} \oplus \underbrace{}_{4}$$X_{1} \oplus X_{4} \oplus Y^{4}$ |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

## What does the linear approximations mean

$$
X_{3} \oplus X_{4} \oplus Y_{1} \oplus Y_{4}
$$

- If we do the following
while(large number of times) \{ generate a random plaintext
$z=e x-o r\left(x_{3}, x_{4}, y_{1}, y_{4}\right)$
\}
- The probability that $z$ takes the value 0 is $1 / 8$

How do we use this fact to attack the block cipher?

## Piling-up Lemma

Consider two linear combinations of random variables

$$
\begin{array}{ll}
X_{A}=X_{1} \oplus X_{2} \oplus X_{3} & \text { having bias } \varepsilon_{A} \\
X_{B}=X_{4} \oplus X_{5} \oplus X_{6} & \text { having bias } \varepsilon_{B}
\end{array}
$$

What is the bias of $X_{A} \oplus X_{B}$ ?
The resulta nt bias $\varepsilon_{A B}$ can be computed by the Pilingup Lemma

LEMMA (Piling-up lemma) Let $\epsilon_{i_{1}, i_{2}, \ldots, i_{k}}$ denote the bias of the random variable $\mathbf{X}_{\mathbf{i}_{\mathbf{1}}} \oplus \cdots \oplus \mathbf{X}_{\mathbf{i}_{\mathbf{k}}}$. Then

$$
\epsilon_{i_{1}, i_{2}, \ldots, i_{k}}=2^{k-1} \prod_{j=1}^{k} \epsilon_{i_{j}} .
$$

Proof by Mathematical Induction

## The General Attack

## Scheme

1. Use piling up lemma to identify linear trails in the cipher, which have high bias.

- Compute the bias till the pen-ultimate round

2. To determine $\mathbf{k}=\left(\mathrm{K}_{5,5}--\mathrm{K}_{5,8}\right)$ do the following
a. Guess the value of $\mathbf{k}$ ( $\mathbf{1 6}$ possibilities)
b. Compute $\mathrm{S}^{-1}\left(\mathbf{k}^{\wedge} \mathrm{c}_{\mathrm{i}}\right)$ for each ciphertext (we get a distribution)
c. Determine if the bias matches the theoretical estimates.

Applying Piling-up Lemma for the cipher

Find paths which are highly biased

$$
\begin{array}{ll}
\mathbf{T}_{1}=\mathbf{U}_{5}^{1} \oplus \mathbf{U}_{7}^{1} \oplus \mathbf{U}_{\mathbf{8}}^{1} \oplus \mathbf{V}_{6}^{1} & =\mathbf{X}_{\mathbf{5}} \oplus \mathbf{K}_{5}^{1} \oplus \mathbf{X}_{\mathbf{7}} \oplus \mathbf{K}_{7}^{1} \oplus \mathbf{X}_{\mathbf{8}} \oplus \mathbf{K}_{\mathbf{8}}^{1} \oplus \mathbf{V}_{6}^{1} \\
\mathbf{T}_{\mathbf{2}}=\mathbf{U}_{6}^{2} \oplus \mathbf{V}_{6}^{2} \oplus \mathbf{V}_{8}^{2} & =\mathbf{V}_{6}^{1} \oplus \mathbf{K}_{6}^{2} \oplus \mathbf{V}_{6}^{2} \oplus \mathbf{V}_{8}^{2} \\
\mathbf{T}_{3}=\mathbf{U}_{6}^{3} \oplus \mathbf{V}_{6}^{3} \oplus \mathbf{V}_{8}^{3} & =\mathbf{V}_{6}^{\mathbf{2}} \oplus \mathbf{K}_{6}^{3} \oplus \mathbf{V}_{6}^{3} \oplus \mathbf{V}_{8}^{3} \\
\mathbf{T}_{4}=\mathbf{U}_{14}^{3} \oplus \mathbf{V}_{14}^{3} \oplus \mathbf{V}_{16}^{3} & =\mathbf{V}_{\mathbf{8}}^{\mathbf{2}} \oplus \mathbf{K}_{14}^{3} \oplus \mathbf{V}_{14}^{3} \oplus \mathbf{V}_{16}^{3} .
\end{array}
$$

## $\mathrm{T}_{\mathbf{1}} \oplus \mathbf{T}_{\mathbf{2}} \oplus \mathrm{T}_{\mathbf{3}} \oplus \mathbf{T}_{\mathbf{4}}$

$\mathbf{X}_{\mathbf{5}} \oplus \mathbf{X}_{\mathbf{7}} \oplus \mathbf{X}_{\mathbf{8}} \oplus \mathbf{V}_{\mathbf{6}}^{\mathbf{3}} \oplus \mathbf{V}_{\mathbf{8}}^{\mathbf{3}} \oplus \mathbf{V}_{\mathbf{1 4}}^{\mathbf{3}} \oplus \mathbf{V}_{\mathbf{1 6}}^{\mathbf{3}}$

$$
\oplus \mathbf{K}_{\mathbf{5}}^{\mathbf{1}} \oplus \mathbf{K}_{7}^{1} \oplus \mathbf{K}_{\mathbf{8}}^{1} \oplus \mathbf{K}_{\mathbf{6}}^{\mathbf{2}} \oplus \mathbf{K}_{6}^{\mathbf{3}} \oplus \mathbf{K}_{14}^{3}
$$

has bias equal to $2^{3}(1 / 4)(-1 / 4)^{3}=-1 / 32$.

$\mathbf{X}_{\mathbf{5}} \oplus \mathbf{X}_{\mathbf{7}} \oplus \mathbf{X}_{\mathbf{8}} \oplus \mathbf{V}_{\mathbf{6}}^{\mathbf{3}} \oplus \mathbf{V}_{\mathbf{8}}^{\mathbf{3}} \oplus \mathbf{V}_{14}^{\mathbf{3}} \oplus \mathbf{V}_{\mathbf{1 6}}^{\mathbf{3}}$

$$
\oplus \mathbf{K}_{\mathbf{5}}^{\mathbf{1}} \oplus \mathbf{K}_{7}^{1} \oplus \mathbf{K}_{\mathbf{8}}^{1} \oplus \mathbf{K}_{6}^{\mathbf{2}} \oplus \mathbf{K}_{6}^{\mathbf{3}} \oplus \mathbf{K}_{\mathbf{1 4}}^{3}
$$

From the cipher

$$
\begin{aligned}
\mathbf{V}_{6}^{3} & =\mathbf{U}_{6}^{4} \oplus \mathbf{K}_{6}^{4} \\
\mathbf{V}_{8}^{3} & =\mathbf{U}_{14}^{4} \oplus \mathbf{K}_{14}^{4} \\
\mathbf{V}_{14}^{3} & =\mathbf{U}_{\mathbf{8}}^{4} \oplus \mathbf{K}_{8}^{4} \\
\mathbf{V}_{16}^{3} & =\mathbf{U}_{16}^{4} \oplus \mathbf{K}_{16}^{4}
\end{aligned}
$$

Thus,
$\mathbf{X}_{\mathbf{5}} \oplus \mathbf{X}_{\mathbf{7}} \oplus \mathbf{X}_{\mathbf{8}} \oplus \mathbf{U}_{\mathbf{8}}^{4} \oplus \mathbf{U}_{\mathbf{8}}^{4} \oplus \mathbf{U}_{\mathbf{1 4}}^{4} \oplus \mathbf{U}_{\mathbf{1 8}}^{4}$
$\oplus \mathbf{K}_{\mathbf{5}}^{1} \oplus \mathbf{K}_{\mathbf{7}}^{1} \oplus \mathbf{K}_{\mathbf{8}}^{1} \oplus \mathbf{K}_{\mathbf{6}}^{\mathbf{2}} \oplus \mathbf{K}_{6}^{3} \oplus \mathbf{K}_{14}^{3} \oplus \mathbf{K}_{\mathbf{6}}^{\mathbf{4}} \oplus \mathbf{K}_{\mathbf{8}}^{\mathbf{4}} \oplus \mathbf{K}_{\mathbf{1 4}}^{4} \oplus \mathbf{K}_{18}^{4}$
has bias equal to $2^{3}(1 / 4)(-1 / 4)^{3}=-1 / 32$.
Now,, the key part is a constant (either 0 or 1)
$\mathbf{K}_{\mathbf{5}}^{\mathbf{1}} \oplus \mathbf{K}_{\mathbf{7}}^{\mathbf{1}} \oplus \mathbf{K}_{\mathbf{8}}^{\mathbf{1}} \oplus \mathbf{K}_{\mathbf{6}}^{\mathbf{2}} \oplus \mathbf{K}_{\mathbf{6}}^{\mathbf{3}} \oplus \mathbf{K}_{\mathbf{1 4}}^{\mathbf{3}} \oplus \mathbf{K}_{\mathbf{6}}^{\mathbf{4}} \oplus \mathbf{K}_{\mathbf{8}}^{\mathbf{4}} \oplus \mathbf{K}_{\mathbf{1 4}}^{4} \oplus \mathbf{K}_{16}^{4}$

Thus, bias of $\mathbf{X}_{5} \oplus \mathbf{X}_{7} \oplus \mathbf{X}_{\boldsymbol{8}} \oplus \mathrm{U}_{\mathbf{6}}^{4} \oplus \mathrm{U}_{\mathbf{8}}^{4} \oplus \mathbf{U}_{14}^{4} \oplus \mathbf{U}_{16}^{4}$ is either $+1 / 32$ or $-1 / 32$ depending on the key bits

## The Linear Cryptanalysis Attack

- The attacker needs
- A large number of plaintext-ciphertext pairs
- We denote each pair by $(x, y)-x$ : plaintext, $y$ : ciphertext
- For the Toy cipher above (approx 8000)
- For a cipher like DES $2^{48}$
- all plaintexts are encrypted with the same key
- The attack

1. Guess $k_{<22}^{5}$ and $k_{<4>}^{5} \quad$ (256 possibilities)
2. For each $y_{<2\rangle}^{5}$ and $y_{<4\rangle}^{5}$ compute $v_{<2\rangle}^{4}$ and $v_{<4\rangle}^{4}$
3. Then compute inv-sbox $\left(v_{<2\rangle}^{4}\right)$ and inv-sbox $\left(v_{<4\rangle}^{4}\right)$ to obtain $u_{<2\rangle}^{4}$ and $u_{<4\rangle}^{4}$
4. Now compute

$$
z \leftarrow x_{5} \oplus x_{7} \oplus x_{8} \oplus u_{6}^{4} \oplus u_{8}^{4} \oplus u_{14}^{4} \oplus u_{16}^{4}
$$

If the key guess is correct, the bias of $z$ must be $\pm 1 / 32$

(i.e. z must be 0 (or 1 ) with probability $1 / 2 \pm 1 / 32$ ) If the key guess is wrong, the bias of $z$ must be 0 (i.e. z must be 0 (or 1 ) with probability $1 / 2$ )

## The Linear Cryptanalysis Attack

## Differential Cryptanalysis

## Differential Cryptanalysis

- Attributed to Eli Biham and Adi Shamir in CRYPTO'90
- Althought, the idea was known in the 1970s by IBM (and the NSA)
- In IBM, this used to be known as T-attack or Tickle attack
- Differential cryptanalysis is a chosen plaintext attack
- It requires $2^{47}$ chosen plaintexts to break DES

## Differentials

- If we have two Boolean linear equations such as

$$
A=a \oplus b \oplus k_{1} \oplus k_{2} \quad B=c \oplus d \oplus k_{1} \oplus k_{2}
$$

- Then, the differential is their ex-or

$$
A \oplus B=a \oplus b \oplus c \oplus d
$$

- Note that the common terms are cancelled out

## Differentials of an s-box

$$
R_{p}\left(a^{\prime}, b^{\prime}\right)=\frac{N_{D}\left(a^{\prime}, b^{\prime}\right)}{2^{m}}
$$

Probability that output difference Is b' given that input difference is $a^{\prime}$

This is known as the
Propagation Ratio

## Differential trails in a cipher

- First note that the differential output $y$ ' does not depend on the secret key
- Choose a set of consecutive s-boxes so that differences propagate with high propagation ratio. This is the differential trail.
- In $S_{2}^{1}, R_{p}(1011,0010)=1 / 2$
- In $S_{3}^{2}, R_{p}(0100,0110)=3 / 8$
- In $S_{2}^{3}, R_{p}(0010,0101)=3 / 8$
- In $S_{3}^{3}, R_{p}(0010,0101)=3 / 8$
- Assuming independence between the s-boxes in the trail, propagation ratio for the trail is the product of individual propagation ratios.

$$
R_{p}(0000101100000000,0000010101010000)=\frac{1}{2} \times\left(\frac{3}{8}\right)^{3}=\frac{27}{1024}
$$

- This means that, if the input difference is (0000 10110000 0000) then the probability that the output difference is (0000 010101010000 ) is $27 / 1024$

## The Differential Cryptanalysis Attack

- The attacker needs
- A large number of chosen plaintext-ciphertext pairs encrypted with the same key
- The attack

1. Guess $k_{<2>}^{5}$ and $k_{<4>}^{5} \quad$ (256 possibilities)
2. Compute $v_{<2\rangle}^{4}$ and $v_{<4\rangle}^{4}$ for each plaintext-ciphertext
 using the guessed key
3. Compute the difference between the inv-sbox $\left(v_{<2\rangle}^{4}\right)$ and inv-sbox $\left(v_{<4>}^{4}\right)$
4. Test if the required differential is obtained.

If the key guess is correct, the correct differential will be obtained with a probability of 27/1024
If the key guess is wrong, the differential will be obtained with a probability which is much lower $(1 / 256)$

## The Differential Cryptanalysis Algorithm

# DES <br> (Data Encryption Standard) 

## History of DES

- Standardized in 1977 by FIPS, as the standard for data encryption
- Based on a Feistel cipher called Lucifer (Lucifer is a Feistel cipher developed by IBM in the early '70s)
- NSA made some minor (supposedly controversial) modifications to the Lucifer algorithm
- Reduced the key size from 64 bits to 56 bits
- Modifications to the s-boxes

## DES Specification

Plaintext ( 64 bits)

- Block Size : 64 bits
- Key size : 56 bits (+8 parity bits)
- Structure : Fiestel
- Rounds:16
- Algorithm specifies :
encryption / decryption algorithm key expansion algorithm

## DES Initial and Final Permutation

- Plaintext subjected to an Initial permutation (IP) initially
- After 16 rounds, there is a final permutation (FP) before the ciphertext is generated
neither operation has any cryptographic significance. Used to facilitate loading of blocks in and out of 1970s eight bit computer

## IP and FP

## Initial Permutation (IP)

| 58 | 50 | 42 | 34 | 26 | 18 | 10 | 2 |
| :--- | :--- | :--- | :--- | :--- | :--- | ---: | ---: |
| 60 | 52 | 44 | 36 | 28 | 20 | 12 | 4 |
| 62 | 54 | 46 | 38 | 30 | 22 | 14 | 6 |
| 64 | 56 | 48 | 40 | 32 | 24 | 16 | 8 |
| 57 | 49 | 41 | 33 | 25 | 17 | 9 | 1 |
| 59 | 51 | 43 | 35 | 27 | 19 | 11 | 3 |
| 61 | 53 | 45 | 37 | 29 | 21 | 13 | 5 |
| 63 | 55 | 47 | 39 | 31 | 23 | 15 | 7 |

The first bit of the o/p is taken from the $58^{\text {th }}$ input bit

## Final Permutation (FP $=\mathrm{IP}^{-1}$ )

| 40 | 8 | 48 | 16 | 56 | 24 | 64 | 32 |
| ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| 39 | 7 | 47 | 15 | 55 | 23 | 63 | 31 |
| 38 | 6 | 46 | 14 | 54 | 22 | 62 | 30 |
| 37 | 5 | 45 | 13 | 53 | 21 | 61 | 29 |
| 36 | 4 | 44 | 12 | 52 | 20 | 60 | 28 |
| 35 | 3 | 43 | 11 | 51 | 19 | 59 | 27 |
| 34 | 2 | 42 | 10 | 50 | 18 | 58 | 26 |
| 33 | 1 | 41 | 9 | 49 | 17 | 57 | 25 |

This is the inverse of IP

## DES F Function (E and Key mixing)

 bit input is expanded to 48 bits by duplicating some of the bits key mixing with subkey,

Expansion Function

## DES F Function (S-boxes)

Select 48 out of the 56 bits

## DES Decryption

- Same as encryption algorithm, with subkeys applied in reverse order

## DES Weak Keys

- In a DES weak key, all the subkeys are the same

Thus $\operatorname{DES}_{W_{K}}\left(\right.$ DES $\left._{W K}(x)\right)=x$ (WK is a weak key)

- DES weak keys are as follows

| 56 bit DES weak keys |
| :--- |
| $0000000 \quad 0000000$ |
| FFFFFFF FFFFFFF |
| 0000000 FFFFFFF |
| FFFFFFF 0000000 |

## DES Semi weak keys

- Semi-weak keys have the following properties
- They appear in pairs: (SK1 and SK1')
- $\operatorname{DES}_{\mathrm{SK} 1}\left(\mathrm{DES}_{\mathrm{SK} 1}(\mathrm{x})\right)=\mathrm{x}$
- Each semi-weak key has only two sub keys.

|  | SK1 | SK1' |
| :---: | :---: | :---: |
| 1 | 9153E54319BD | 6EAC1ABCE642 |
| 2 | 6EAC1ABCE642 | 9153E54319BD |
| 3 | 6EAC1ABCE642 | 9153E54319BD |
| 4 | 6EAC1ABCE642 | 9153E54319BD |
| 5 | 6EAC1ABCE642 | 9153E54319BD |
| 6 | 6EAC1ABCE642 | 9153E54319BD |
| 7 | 6EAC1ABCE642 | 9153E54319BD |
| 8 | 6EAC1ABCE642 | 9153E54319BD |
| 9 | 9153E54319BD | 6EAC1ABCE642 |
| 10 | 9153E54319BD | 6EAC1ABCE642 |
| 11 | 9153E54319BD | 6EAC1ABCE642 |
| 12 | 9153E54319BD | 6EAC1ABCE642 |
| 13 | 9153E54319BD | 6EAC1ABCE642 |
| 14 | 9153E54319BD | 6EAC1ABCE642 |
| 15 | 9153E54319BD | 6EAC1ABCE642 |
| 16 | 6EAC1ABCE642 | 9153E54319BD |

## DES Semi weak key pairs

| First key in the pair | Second key in the pair |
| :--- | :--- |
| 01FE 01FE 01FE 01FE | FE01 FE01 FE01 FE01 |
| 1FE0 1FE0 0EF1 0EF1 | E01F E01F F10E F10E |

## Objections to DES

- Key size matters
- Brute Force Attacks due to the small key size
- S-box secrecy
- During the initial years, the rationale for the DES s-box was kept secret (... to increase security).
- Mathematical attacks :
- Differential Cryptanalysis
- Linear Cryptanalysis

## DES Cracker

- Specialized ASICs for DES bruteforce
- Could determine the secret key in less than a day
.... Need to increase key length!!

## DES Composition

- Key size can be increased by composition

$$
\mathrm{C}=\mathrm{DES}_{\mathrm{K} 1}\left(\mathrm{DES}_{\mathrm{K} 2}(\mathrm{P})\right)
$$

- DES does not form a group under composition. i.e. It is not possible to obtain
$\mathrm{DES}_{\mathrm{K} 1}\left(\mathrm{DES}_{\mathrm{K} 2}(\mathrm{P})\right)=\mathrm{DES}_{\mathrm{K} 3}(\mathrm{P})$ for some key K3

## Meet in the Middle Attack

 against 2-DES

- Attacker collects a pair of (P,C)

1. For $P$, compute $Q_{K 1^{*}}=D E S_{K 1^{*}}(P)$ for every possible value of $K 1^{*}$. Record the corresponding $\mathrm{Q}_{11^{*}}$
2. For C, compute $\mathrm{Q}_{\mathrm{K} 2^{*}}=\mathrm{DES}^{-1} \mathrm{K2}^{*}(\mathrm{C})$ for every possible value of $\mathrm{K} 2^{*}$. Record the corresponding $\mathrm{Q}_{\mathrm{K} 2^{*}}$
3. Find all $\mathrm{K} 1^{*}$ and $\mathrm{K} 2^{*}$ such that $\mathrm{Q}_{\mathrm{K} 1^{*}}=\mathrm{Q}_{\mathrm{K} 2^{*}}$
4. If Multiple such K1* and K2* are found, then repeat with another pair of (P,C)

- Complexity of this attack is $2^{56}+2^{56}=2^{57}$

## 3-DES

- 112 bit security as in 2-DES
- Encrypt $\rightarrow$ Decrypt $\rightarrow$ Encrypt
- K1 $\rightarrow$ K2 $\rightarrow$ K1 (two 56 bit keys)
- Why EDE and not EEE?
- Compatibility with the classical DES if $\mathrm{K}_{1}=\mathrm{K}_{2}$
- Used extensively as a stopgap arrangement until a new cipher standard (AES) was established
- Drawbacks of 3-DES:
- Sluggish in software
- Could only encrypt 64 bit blocks at a time

Modes of Operation

## What are Modes of Operation?

- Block cipher algorithms only encrypt a single block of message
- A mode of operation describes how to repeatedly apply a cipher's single-block operation to securely transform amounts of data larger than a block
- Modes of Operation
- Electronic code book mode (ECB Mode)
- Cipher feedback mode (CFB Mode)
- Cipher block chaining mode (CBC mode)
- Output feedback mode (OFB mode)
- Counter mode

## ECB Mode

- Every block in the message is encrypted independently with the same key
- Drawback 1 : If $p_{i}=p_{j}(i \neq j)$ then $c_{i}=c_{j}$
- Encryption should protect against known plaintext attacks (since the attacker could guess parts of the message..... Like stereotype beginnings)
- Drawback 2 : An interceptor may alter the order of the blocks during transmission
- Not recommended for encryption of more than one block

## CBC Mode

- Cipher Block Chaining
- Advantage 1 : Encryption dependent on a the ciphertext of a previous block, therefore
$-c_{i} \neq c_{j} \quad(i \neq j)$ even if $p_{i}=p_{j}$
- Advantage 2: Intruder cannot alter the order of the blocks during transmission
- If an error is present in one received block (say $c_{i}$ )
- Then $c_{i}$ and $c_{i+1}$ will not be decrypted correctly
- All remaining blocks will be correctly decrypted

## CBC Mode Decryption <br> p1 <br> p2 <br> p3 <br> p4

## CFB (Cipher feedback Mode)

Can transform a block cipher into a stream cipher.

- i.e. Each block encrypted with a different key

Uses a shift register that is initialized with an IV

Encryption Scheme

## CFB - Error Propagation

Uses a shift register that is initialized with an IV Previous ciphertext block fed into shift register

Decryption Scheme

## Output Feedback Mode (OFB)

- Very similar to CFB but feedback taken from output of $\mathrm{e}_{\mathrm{k}}$
- An error in one byte of the ciphertexts affects only one decryption

Encryption Scheme<br>(Decryption scheme is similar)

## Counter Mode

- A randomly initialized counter is incremented with every encryption
- Can be parallelized
- le. Multiple encryption engines can simultaneously run
- As with OFB, an error in a single ciphertext block affects only one decrypted plaintext

## How to choose a good s-box?

Mod-01, Lec-07, Overview of S-box Principles, by Debdeep Mukhopadhyay https://www.youtube.com/watch?v=cJ7hmwHVwtc\&list=PL71FE85723FD414D7\&index=17

## Criteria for a good s-box

- Completeness
- Balance
- Non-linearity
- Propagation criteria
- Good XOR profile
- High Algebraic Degree

## Sboxes

- In an s-box each output bit can be represented as a Boolean function of its input bits

$$
\begin{aligned}
& y_{1}=f_{1}\left(x_{1}, x_{2}, x_{3}, \cdots, x_{m}\right) \\
& y_{2}=f_{2}\left(x_{1}, x_{2}, x_{3}, \cdots, x_{m}\right) \\
& y_{3}=f_{3}\left(x_{1}, x_{2}, x_{3}, \cdots, x_{m}\right) \\
& \vdots \quad \vdots \quad \vdots \quad \vdots \quad \vdots \\
& y_{n}=f_{n}\left(x_{1}, x_{2}, x_{3}, \cdots, x_{m}\right)
\end{aligned}
$$

The functions have to be non-linear. Linear functions are easily reversed.

## Boolean Functions

- A Boolean function is a mapping from $\{0,1\}^{m} \rightarrow\{0,1\}$
- Algebraic Normal Form representation of a Boolean function
- A Boolean function on m-inputs can be represented with sum (XOR +) of products (AND .) form:

$$
y=a_{0} \oplus a_{1} x_{1} \oplus a_{2} x_{2} \oplus a_{3} x_{1} x_{2}
$$

where $\mathrm{a}_{\mathrm{i}}$ is either 0 or 1 .

- Affine Form: if all the terms have coefficients $0\left(a_{3}=0\right.$ in the above example)
- Linear form : Affine form and $\mathrm{a}_{0}=0$

## Truth Tables

- Consider a Boolean function $f:\{0,1\}^{m} \rightarrow\{0,1\}$
- The following Binary sequence is the truth table of f
$\left(f\left(\alpha_{0}\right), f\left(\alpha_{1}\right), f\left(\alpha_{2}\right), \cdots, f\left(\alpha_{2^{m-1}}\right)\right)$

| $X_{1}$ | $X_{2}$ | $Y$ |
| :--- | :--- | :--- |
| 0 | 0 | 0 |
| 0 | 1 | 1 |
| 1 | 0 | 1 |
| 1 | 1 | 1 |

- Sequence is (1,-1,-1,-1)

## Balanced Boolean Functions

- A Boolean function is said to be balanced if its truth table has equal number of 0 s and 1 s .
- S-box equations should be balanced (i.e. 0 and 1 have an equal probability of occurrence)

## Distance Between functions

Let $f$ and $g$ be two Boolean functions
Let $\eta$ be the truth table for $f$ and $\varepsilon$ the truth table for $g$
$H D(\eta, \varepsilon)$ is the Hamming distance between the two sequences

| $\mathrm{X}_{1}$ | $\mathrm{X}_{2}$ | $\mathrm{Y}_{1}$ | $\mathrm{Y}_{2}$ |
| :--- | :--- | :--- | :--- |
| 0 | 0 | 0 | 0 |
| 0 | 1 | 1 | 1 |
| 1 | 0 | 1 | 1 |
| 1 | 1 | 1 | 0 |

$$
\begin{gathered}
f: y_{1}=x_{1} \oplus x_{2} \oplus x_{1} x_{2} \\
g: y_{2}=x_{1} \oplus x_{2}
\end{gathered}
$$

$$
H D(\eta, \varepsilon)=1
$$

## Nonlinearity of a Boolean Function

- The non-linearity of a Boolean function is the minimum distance between the function and the set of all linear functions.
- Strengthens against linear cryptanalysis

$$
\begin{aligned}
& y_{1}=x_{1} \oplus x_{2} \oplus x_{1} x_{2} \\
& y_{2}=0 \\
& y_{3}=x_{1} \\
& y_{4}=x_{2} \\
& y_{5}=x_{1} \oplus x_{2}
\end{aligned}
$$

| $\mathrm{X}_{1}$ | $\mathrm{X}_{2}$ | Y 1 | Y 2 | Y 3 | $\mathrm{Y}_{4}$ | $\mathrm{Y}_{5}$ |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| 0 | 1 | 1 | 0 | 0 | 1 | 1 |
| 1 | 0 | 1 | 0 | 1 | 0 | 1 |
| 1 | 1 | 1 | 0 | 1 | 1 | 0 |

Nonlinearity: $N_{f}=\operatorname{MIN}_{g \varepsilon \text { linear }}(H D(f, g))$
Nonlinearity of $y_{1}: N_{y_{1}}=1$
$\longleftarrow 1$
$\longleftrightarrow 1$
$\longleftarrow 1$

## Walsh Hadamand Matrix

- A compact combinatorial representation of all affine functions
- Each row of the WH matrix forms the truth table of all affine functions with N variables can be represented by the matrix

$$
\begin{aligned}
& H\left(2^{N}\right)=\left[\begin{array}{cc}
H\left(2^{N-1}\right) & H\left(2^{N-1}\right) \\
H\left(2^{N-1}\right) & \text { complement }\left(H\left(2^{N-1}\right)\right)
\end{array}\right] \\
& H\left(2^{1}\right)=\left[\begin{array}{ll}
0 & 0 \\
0 & 1
\end{array}\right] \longrightarrow \mathrm{x}_{1} \\
& H\left(2^{2}\right)=\left[\begin{array}{llll}
0 & 0 & 0 & 0 \\
0 & 1 & 0 & 1 \\
0 & 0 & 1 & 1 \\
0 & 1 & 1 & 0
\end{array}\right] \mathrm{x}_{2} \\
& \mathrm{x}_{1} \\
& \mathrm{x}_{2} \wedge \mathrm{x}_{1}
\end{aligned}
$$

## On the Non-linearity of Boolean Functions

- HD of any two linear functions is always $2^{n-1}$
- HD between two non-linear functions is < $2^{n-1}$

Scalar product

$$
\begin{aligned}
& \begin{array}{l}
\operatorname{Let}\langle\xi, \eta\rangle=\#(f=g)-\#(f \neq g) \\
=2^{n}-\#(f \neq g)-\#(f \neq g) \\
=2^{n}-2 \#(f \neq g)
\end{array} \\
& \operatorname{HD}(f, g)=\#(f \neq g)=2^{n-1}-\frac{1}{2}\langle\xi, \eta\rangle
\end{aligned}
$$

## Bent Functions

- Bent functions are non-linear Boolean functions which have maximum non-linearity
- The non-linearity of a Bent function is $2^{n-1}-2^{\frac{n}{2}-1}$
- They satisfy SAC but are not balanced
- Example : $f(x)=x_{1} x_{2}+x_{3} x_{4}$

## Affine Transformations and Non-linearity

- If a Boolean function is balanced, then an affine transformation does not affect its non-linearity
$f(x)$ is a balanced Boolean function, then $f(x B \oplus A)$ is also balanced $x=\left(x_{1}, x_{2}, x_{3}, \ldots, x_{n}\right)$
$B$ is a $n \times n$ binary invertible matrix
$A$ is an $n$ bit vector
The nonlinearity of $f(x)=$ nonlinearity of $f(x B \oplus A)$

## Strict Avalanche Criteria (SAC)

- For a function (f) to satisfy SAC,
$f(x) \oplus f(x \oplus \alpha)$ must be balanced, for any $\alpha$ with $H W(\alpha)=1$
- Also called propagation criteria of order 1
- Higher order SAC,
- Propagation criteria of order > 1
- When input changes in more than 1 bit
- Show that
$y=x_{1} x_{2} \oplus x_{3} \quad$ does not satisfy $S A C$
$z=x_{1} x_{2} \oplus x_{3} x_{4}$ satisfies $S A C$
Note that z is a Bent function

## How to make a Boolean function satisfy SAC

- Let $f(x)$ be a Boolean function of order n
- Let A be an nxn non-singular Boolean matrix
- If r is a row in the matrix A and $f(x) \oplus f(x \oplus r)$ is balanced then $g(x)=f(x A)$ satisfies SAC

Example:

$$
\begin{aligned}
& f=x_{1} x_{2} \oplus x_{3} \\
& A=\left[\begin{array}{lll}
1 & 0 & 0 \\
0 & 1 & 0 \\
1 & 1 & 1
\end{array}\right] \\
& \text { then } g(x)=f(x A) \text { satisfies } S A C
\end{aligned}
$$

## Completeness

- More a criteria for the complete cipher (SP)
- Given s-boxes with a fixed mapping,
- P-layer needs to be fixed and rounds need to be fixed such that ciphertext is a complex function of every plaintext input

## XOR Profile

- The difference distribution table of the s-box must contain small variations

## The Advanced Encryption Standard (AES)

## Advanced Encryption Standard (AES)

- NIST's standard for block cipher since October 2000.

|  | Key <br> Length | No. of <br> rounds |
| :--- | :--- | :--- |
| AES-128 | 16 bytes | 10 |
| AES-192 | 24 bytes | 12 |
| AES-256 | 32 bytes | 14 |

- SPN network with each round having
- Randomness Layer: Round key addition
- Confusion Layer : Byte Substitution
- Diffusion Layer : Shift row and Mix column
(the last round does not have mix column step)

## Mathematical Background

## Finite Fields

## The AES State Representation

16 byte plaintext
$a b c|d e f / g h i j k| m n o p$

- 16 bytes arranged in a $4 \times 4$ matrix of bytes

## AES-128 Encryption

Plaintext
Block

4 Operations

- Byte Substitution
- Shift Rows
- Mix Columns
- Add Round Key

Ciphertext
Block

## AES-128 Encryption

## AES Operations

- All AES operations are performed in the field GF( $2^{8}$ ).
- The field's irreducible polynomial is

$$
x^{8}+x^{4}+x^{3}+x+1
$$

in binary notation (1 0001 1011) ${ }_{2}$
in hex notation (11B) ${ }_{16}$

## Byte Substitution

- Makes a non-linear substitution for every byte in the $4 \times 4$ matrix

Affine Transformation
$\operatorname{Sbox}(A)= \begin{cases}\operatorname{Affine}\left(A^{-1}\right) & \text { if } A(\theta) \neq 0 \\ \operatorname{Affine}(0) & \text { if } A(\theta)=0\end{cases}$
$=\left[\begin{array}{llllllll}1 & 1 & 1 & 1 & 1 & 0 & 0 & 0 \\ 0 & 1 & 1 & 1 & 1 & 1 & 0 & 0 \\ 0 & 0 & 1 & 1 & 1 & 1 & 1 & 0 \\ 0 & 0 & 0 & 1 & 1 & 1 & 1 & 1 \\ 1 & 0 & 0 & 0 & 1 & 1 & 1 & 1 \\ 1 & 1 & 0 & 0 & 0 & 1 & 1 & 1 \\ 1 & 1 & 1 & 0 & 0 & 0 & 1 & 1 \\ 1 & 1 & 1 & 1 & 0 & 0 & 0 & 1\end{array}\right]\left[\begin{array}{l}a_{7} \\ a_{6} \\ a_{5} \\ a_{4} \\ a_{3} \\ a_{2} \\ a_{1} \\ a_{0}\end{array}\right] \oplus\left[\begin{array}{l}0 \\ 1 \\ 1 \\ 0 \\ 0 \\ 0 \\ 1 \\ 1\end{array}\right]$

## AES S-box Design Rationale

$$
\operatorname{Sbox}(A)= \begin{cases}\operatorname{Affine}\left(A^{-1}\right) & \text { if } A(\theta) \neq 0 \\ \operatorname{Affine}(0) & \text { if } A(\theta)=0\end{cases}
$$

- This s-box construction was proposed by Kaiser Nyberg in 1993
- Steps:

1. Inverse in $\mathrm{GF}\left(2^{8}\right)$

- Provides high degrees of non-linearity
- Known to have good resistance against differential and linear cryptanalysis

2. Affine transformation

- ensures no fixed points : i.e. Fixed points : $S(x)=x$
- Complicates Algebraic attacks

## S-box Encryption Table

- Use a table to do the byte substitution
- eg. Sbox[42]=2c

|  |  | Y |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  | 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | a | b | c | d | e | f |
| x | 0 | 63 | 7 c | 77 | 7b | f2 | 6b | 6 f | c5 | 30 | 01 | 67 | 2b | fe | d7 | ab | 76 |

|  | f | 8c | a1 | 89 | 0d | bf | e6 | 42 | 68 | 41 | 99 | 2 d | 0 f | b0 | 54 | bb | 16 |

## Shift Rows

| $a$ | $e$ | $i$ | $m$ |
| :---: | :---: | :---: | :---: |
| $b$ | $f$ | $j$ | $n$ |
| $c$ | $g$ | $k$ | $o$ |
| $d$ | $h$ | $l$ | $p$ |$\quad \longrightarrow$| $a$ | $e$ | $i$ | $m$ |
| :---: | :---: | :---: | :---: |
| $f$ | $j$ | $n$ | $b$ |
| $k$ | $o$ | $c$ | g |
| $p$ | $d$ | $h$ | $l$ |

- ShiftRows
- Leave the First row untouched
- Left Rotate ( $2^{\text {nd }}$ Row by 8 bits)
- Left Rotate (3rd Row by 16 bits)
- Left Rotate ( $4{ }^{\text {th }}$ Row by 24 bits)
- Along with MixColumns provides high diffusion
- Bits flip in at-least 25 s-boxes after 4 rounds

## Mix Columns

## The $4 \times 4$ matrix is multiplied with the matrix

$$
\left[\begin{array}{llll}
2 & 3 & 1 & 1 \\
1 & 2 & 3 & 1 \\
1 & 1 & 2 & 3 \\
3 & 1 & 1 & 2
\end{array}\right] \times\left[\begin{array}{llll}
a & e & i & m \\
b & f & j & n \\
c & g & k & o \\
d & h & l & p
\end{array}\right]
$$

Note that multiplications are in GF( $2^{8}$ ) field

## Mix Columns Rationale

Why use this matrix?

- It is an MDS matrix (Maximum Distance Separable codes)
- If the input of a column changes then all
$\left[\begin{array}{llll}2 & 3 & 1 & 1 \\ 1 & 2 & 3 & 1 \\ 1 & 1 & 2 & 3 \\ 3 & 1 & 1 & 2\end{array}\right]$ outputs change
- This maximizes the branch number
- For AES, the branch number is 5
- Values [2, $3,1,1$ ], are the smallest which result in MDS matrix that is also circulant
- Has an inverse in the AES field

## AES Operations (Add Round Key)

| a | e | i | $m$ |
| :---: | :---: | :---: | :---: |
| $b$ | $f$ | j | $n$ |
| c | g | k | $o$ |
| d | h | l | p |

$\bigoplus$| $k_{0}$ | $k_{4}$ | $k_{8}$ | $k_{12}$ |
| :--- | :--- | :--- | :--- |
| $k_{1}$ | $k_{5}$ | $k_{9}$ | $k_{13}$ |
| $k_{2}$ | $k_{6}$ | $k_{10}$ | $k_{14}$ |
| $k_{3}$ | $k_{7}$ | $k_{11}$ | $k_{15}$ |

Addition here is addition in $\operatorname{GF}\left(2^{8}\right)$, which is the ex-or operation

## AES-128 Decryption

Ciphertext Block

## Inverse S-box

- Simply the AES s-box run in reverse
- As with the s-box operation, a lookup table can be used

|  | x 0 | x1 | x2 | x3 | x4 | x5 | x6 | $\times 7$ | x8 | x9 | xa | xb | xc | xd | xe | xf |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 0x | 52 | 09 | 6a | d5 | 30 | 36 | a5 | 38 | bf | 40 | a3 | 9 e | 81 | f3 | d7 | fb |
| 1x | 7 c | e3 | 39 | 82 | 9 b | $2 f$ | ff | 87 | 34 | 8 e | 43 | 44 | c 4 | de | e9 | cb |

## Inverse Shift Rows

| $a$ | $e$ | $i$ | $m$ |
| :---: | :---: | :---: | :---: |
| f | j | n | $b$ |
| b | o | c | g |
| p | d | h | l |

$\longrightarrow \quad$| $a$ | $e$ | $i$ | $m$ |
| :---: | :---: | :---: | :---: |
| $b$ | $f$ | $j$ | $n$ |
| $c$ | $g$ | $k$ | $o$ |
| $d$ | $h$ | $l$ | $p$ |

- ShiftRows
- Leave the First row untouched
- Right Rotate (2 ${ }^{\text {nd }}$ Row by 8 bits)
- Right Rotate (3 ${ }^{\text {rd }}$ Row by 16 bits)
- Right Rotate (4 ${ }^{\text {th }}$ Row by 24 bits)
a

## Inverse Mix Column

- The $4 \times 4$ matrix is multiplied with the matrix
$\left[\begin{array}{cccc}\mathrm{E} & \mathrm{B} & \mathrm{D} & 9 \\ 9 & \mathrm{E} & \mathrm{B} & \mathrm{D} \\ \mathrm{D} & 9 & \mathrm{E} & \mathrm{B} \\ \mathrm{B} & \mathrm{D} & 9 & \mathrm{E}\end{array}\right]$
- The hardware implementation can be done in a similar way as mix columns

## AES Key Schedule

- How to expand the secret key
- Design Criteria

## AES Key Schedule

## Implementation Aspects of AES

## Software Implementations of AES Encryption

- S-box implemented as a lookup-table (256 bytes)
- Shift rows combined with Mix columns
- Multiplication with MDS matrix easily achieved
$-x 2$, done by left shift. If there is an overflow an ex-or with $0 \times 1 B$ is needed
$-x 3=x 2+x$

## AES on 32 bit Systems

## AES state

## Byte Substitution

$$
b_{i, j}=S\left(a_{i, j}\right) \text { for } i, j \in\{0,1,2,3\}
$$

$$
\left[\begin{array}{llll}
a_{0,0} & a_{0,1} & a_{0,2} & a_{0,3} \\
a_{1,0} & a_{1,1} & a_{1,2} & a_{1,3} \\
a_{2,0} & a_{2,1} & a_{2,2} & a_{2,3} \\
a_{3,0} & a_{3,1} & a_{3,2} & a_{3,3}
\end{array}\right]
$$

Shift Rows

$$
\begin{aligned}

\hline PCLMULQDQ & Carryless multiply (CLMUL). \({ }^{[3]}\) \\
\hline
\end{tabular}

\section*{Compact Implementations of AES}
- How should the S-box be implemented?
- Look up table (256 bytes)
- This may be too large for some devices
- Finding the inverse (using Itoh-Tsujii or the extended Euclidean algorithm) and then affine transformation
- Again expensive (too big!!!)
- Third alternative
- Use composite fields

\title{
Composite Fields \\ (refer Math. Background)
}

\section*{Composite Fields for AES}
- The AES Field is GF \(\left(2^{8}\right) / x^{8}+x^{4}+x^{3}+x+1\)
- Has order 256
- Many composite fields for AES exists
\(-\operatorname{GF}\left(2^{4}\right)^{2}\)
- Requires two irreducible polynomials One has the form \(x^{4}+\ldots\). , where coefficients are in GF(2)
The second has the form \(x^{2}+a x+b\), where \(a, b\) are in GF( \(2^{4}\) )
\(-G F\left(\left(2^{2}\right)^{2}\right)^{2}\)
- Requires three irreducible polynomials

First of the form \(x^{2}+a_{1} x+b_{1}\), where \(a_{1}, b_{1}\) in GF(2)
Second has the form \(x^{2}+a_{2} x+b_{2}\), where \(a_{2}, b_{2}\) in GF \(\left(2^{2}\right)\)
Third has the form \(x^{2}+a_{3} x+b_{3}\), where \(a_{3}, b_{3}\) in \(G F\left(2^{2}\right)^{2}\)

\section*{Mapping between \(G F\left(2^{8}\right)\) and Composite Fields}
```

FindMap(){
Initilize MAP[0] = 0 and REVMAP[0] = 0
Find }\alpha\mathrm{ a primitive root of field GF (2 (2)
Find }\beta\mathrm{ a primitive root of field GF(24 )

```

```

    Fori=1 to 255
        \alpha'=\alpha\cdot\alpha' (Multiplication in the field GF (2 (2))
        \beta'=\beta
        MAP[ < '] = 貌
        REVMAP[ [ '}]=\mp@subsup{\alpha}{}{\prime
    return MAP and REVMAP
    }

```

\end{tabular}

\section*{Overhead of Composite Field s-boxes}
- Composite field s-boxes require mapping and reverse mapping to and from the composite fields in each round
- An alternate approach is to convert all other round operations into composite field operations.
- This would require just one mapping and one reverse mapping for the entire encryption
- Operations Add Round Key and Shift Rows are not altered.
- Mix Columns will need to be re-implemented

\section*{Attacks on AES}

\section*{Differential and Linear Properties of AES}
- Differential Cryptanalysis
- No 4 round differential trail >1/2 \({ }^{150}\) and no 8 round differential trail \(>1 / 2^{300}\) exists.
- Linear Cryptanalysis
- No 4 round bias \(>1 / 2^{75}\) and no 8 round bias \(>1 / 2^{150}\) exists

AES can easily resist differential and linear cryptanalysis

\section*{Attack on 4 Rounds of AES}

Plaintext
Block

4 Operations
- Byte Substitution
- Shift Rows
- Mix Columns
- Add Round Key

Ciphertext
Block

\section*{Square Attack}

\section*{(known by the AES designers)}
- Works for 4 round of AES
- Can be extended up to 6 rounds
- Consider 256 plaintext blocks having the following properties
1. byte 0 is different for in all cases (i.e. \(p_{i, 0} \neq p_{j, 0}\) ), for \(i, j=0\) to 255 and \(i \neq j\)
2. bytes 1 to 15 are the same (i.e. \(p_{i, k}=p_{j, k}\) ), for \(i, j=0\) to 255 and \(1 \leq k \leq 15\)

\section*{Square Attack}
- Consider 256 plaintext blocks having the following properties
1. byte 0 is different in all cases (i.e. \(p_{i, 0} \neq p_{j, 0}\) ), for \(i, j=0\) to 255 and \(i \neq j\)
2. bytes 1 to 15 are the same (i.e. \(p_{i, k}=p_{j, k}\) ), for \(i, j=0\) to 255 and \(1 \leq k \leq 15\) Active byte

Two properties
\(\bigoplus_{i=0}^{255} p_{i, k}=0\)
For some k; \(1 \leq k \leq 15\)
The state is balanced
\(\bigoplus_{i=0}^{255} p_{i, 0}=0\)

\section*{Square Attack (Propagation in 3 rounds)}

\section*{Round 1}

Subs Bytes

Mix Columns Add Round Key

Round 2

Round 3
Sub Bytes
Shift Rows
Mix Columns Add Round Key

Mix Columns \(=\oplus_{i=0}^{255}(2 a+3 b+c+d)\)

\[
\begin{aligned}
& =2 \bigoplus_{i=0}^{255} a+3 \bigoplus_{i=0}^{255} b+\bigoplus_{i=0}^{255} c+\bigoplus_{i=0}^{255} d \\
& =0+0+0+0=0
\end{aligned}
\]

\title{
Square Attack

\section*{(Propagation in 3 rounds)}
}

\section*{(Propagation in 3 rounds)}
}

\section*{Round 1}

Mix Columns
Add Round Key

Round 2

Round 3

Shift Rows
Mix Columns Add Round Key

\section*{A 4 round square attack}

\section*{Round 3}

\section*{Sub Bytes \\ Shift Rows \\ Mix Columns Add Round Key}

Round 4

ciphertext
\(S^{-1}\left(E\left(c_{0} \oplus k_{0}\right) \oplus B\left(c_{1} \oplus k_{1}\right) \oplus D\left(c_{2} \oplus k_{2}\right) \oplus 9\left(c_{3} \oplus k_{3}\right)\right)\)

\section*{4 round square attack (A chosen plaintext attack)}
1. Choose 256 plaintexts with one active byte
2. Perform 4 round encryption for each plaintext
3. For each potential key \(\left(k_{0}\left\|k_{1}\right\| k_{2} \| k_{3}\right)\) do the following,
a. Compute \(s_{3,0}\) corresponding to each \(c_{i}\) (there are 256 such \(c_{i}\) )
call them \(s_{3,0}^{(0)}, s_{3,0}^{(1)}, s_{3,0}^{(2)}, \cdots s_{3,0}^{(255)}\)
b. compute \(\oplus_{i=0}^{255} S_{3,0}^{(\mathrm{i})}\)

If this is 0 , then guessed \(\left(k_{0}\left\|k_{1}\right\| k_{2} \| k_{3}\right)\) may be correct If not, guessed key is incorrect

\section*{Why square attack may lead to an}

\section*{incorrect key}

 \(255\}\) with equal probability
- Thus with probability \(2^{-8}\), we may get \(\bigoplus_{t-1}^{255} s_{i 0}^{(1)}=0\) for the wrong key.

\section*{Extending beyond 4 rounds}

Read how the square attack can be extended to 5 rounds and 6 rounds.

\section*{Related Key Attacks on AES (theoretical attacks on full AES)}
- By Alex Biryukov and Dmitry Khovratovich (2009)
- Strong assumption : the attacker forces the victim to choose keys of particular form.
- Determine how key differences affect the cipher text difference

\section*{Tracing key differences}
