# Static Single Assignment (SSA) Form

A sparse program representation for data-flow.

R. Cytron, J. Ferrante, B. K. Rosen, M. N. Wegman, and F. K. Zadeck, Efficiently Computing Static Single Assignment Form and the Control Dependence Graph, ACM TOPLAS 13(4):451–490, Oct 1991

# What is SSA?

- Each assignment to a temporary is given a unique name
- All of the uses reached by that assignment are renamed
- Easy for straight-line code

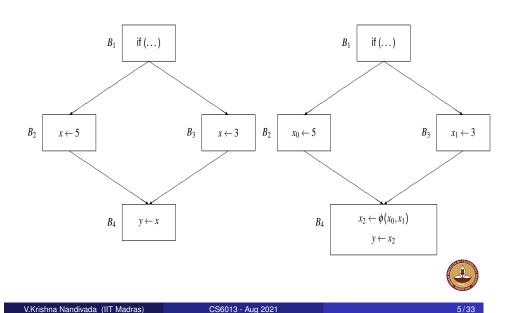

$$\begin{array}{c|cccc}
v \leftarrow 4 & v_0 \leftarrow 4 \\
\leftarrow v + 5 & \leftarrow v_0 + 5 \\
v \leftarrow 6 & v_1 \leftarrow 6 \\
\leftarrow v + 7 & \leftarrow v_1 + 7
\end{array}$$

- What about control flow?
  - $\Rightarrow \phi$ -nodes

V.Krishna Nandivada (IIT Madras) CS6013 - Aug 2021

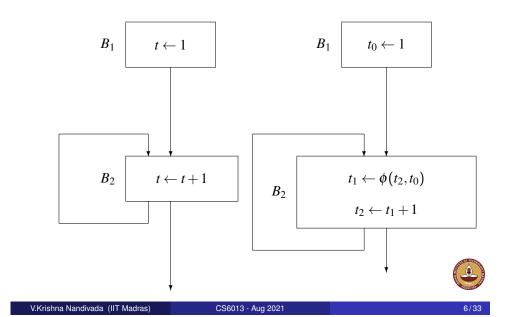

# What is SSA?

# Advantages of SSA over use-def chains

- More compact representation
- Easier to update?
- Each use has only one definition
- ullet Definitions explicitly merge values May still reach multiple  $\phi$ -nodes

# What is SSA?

# "Flavors" of SSA

Where do we place  $\phi$ -nodes?

- [Condition:] If two non-null paths  $x \to^+ z$  and  $y \to^+ z$  converge at node z, and nodes x and y contain assignments to t (in the original program), then a  $\phi$ -node for t must be inserted at z (in the new program)
- [minimal]
   As few as possible subject to condition
- [pruned] As few as possible subject to condition, and no dead  $\phi$ -nodes

# Dominators revisited

### Recall

- d dominates v, d DOM v, in a CFG iff all paths from Entry to v include d
- d strictly dominates v

$$d \text{ DOM! } v \iff d \text{ DOM } v \text{ and } d \neq v$$

DOM(v) = Dominator of v

 $DOM^{-1}(v) = Dominated by v$ 

V.Krishna Nandivada (IIT Madras)

CS6013 - Aug 2021

9/33

# **Dominance Frontiers**

The <u>dominance frontier</u> of v, is the set of nodes  $DF(v) \subseteq CFG.N$  such that,  $w \in DF(v)$ :

- v dominates an immediate predecessor of w, but
- *v* does not strictly dominate *w*.

$$\mathsf{DF}(v) = \{ w \mid (\exists u \in \mathsf{PRED}(w))[v \; \mathsf{DOM} \; u] \land v \; \overline{\mathsf{DOM!}} \; w \}$$

Computing DF:

Let

$$\underline{SUCC}(S) = \bigcup_{s \in S} \underline{SUCC}(s)$$
  
$$DOM!^{-1}(v) = DOM^{-1}(v) - \{v\}$$

Then

$$DF(v) = SUCC(DOM^{-1}(v)) - DOM!^{-1}(v)$$

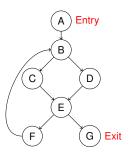

# **Dominator Tree**

**Dominator tree:** a tree where each node's children are those nodes it immediately dominates.

The start node is the root of the tree.

Why is it a tree?

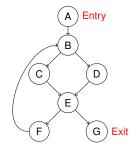

V.Krishna Nandivada (IIT Madras)

CS6013 - Aug 2021

# Iterated Dominance Frontier Algorithm: DF + (S)

```
Input: Set of blocks S
Output: DF +(S)
begin
     workList \leftarrow \{\};
     \mathsf{DF} + (S) \leftarrow \{\};
     foreach n \in S do
          \mathsf{DF} + \overline{(S)} \leftarrow \mathsf{DF} + (S) \cup \{n\};
           workList \leftarrow workList \cup \{n\};
     end
     while workList \neq \{\} do
           take n from workList;
          foreach c \in DF(n) do
                if c \notin DF + (S) then
                     \mathsf{DF} + (S) \leftarrow \mathsf{DF} + (S) \cup \{c\};
                     workList \leftarrow workList \cup \{c\};
                end
           end
     end
end
```

# **Iterated Dominance Frontier**

Extend the dominance frontier mapping from nodes to sets of nodes:

$$\mathsf{DF}(S) = \bigcup_{n \in S} \mathsf{DF}(n)$$

The iterated dominance frontier DF + (S) is the limit of the sequence:

$$\mathsf{DF}_1(S) = \mathsf{DF}(S)$$
  
 $\mathsf{DF}_{i+1}(S) = \mathsf{DF}(S \cup \mathsf{DF}_i(S))$ 

#### Theorem:

The set of nodes that need  $\phi$ -nodes for any temporary t is the iterated dominance frontier DF + (S), where S is the set of nodes that define t

# Inserting $\phi$ -nodes (minimal SSA)

```
foreach t \in Temporaries do S \leftarrow \{n \mid t \in Def(n)\} \cup Entry; Compute DF +(S); foreach n \in DF + (S) do Insert a \phi-node for t at n; end end
```

# Inserting fewest $\phi$ -nodes (pruned SSA)

Compute global liveness: nodes where each temporary is live-in

```
foreach \underline{t} \in \underline{Temporaries} do 

if \underline{t} \in \underline{Globals} then // variables live across multiple basic blocks \underline{S} \leftarrow \{n \mid t \in Defs(n)\} \cup Entry; Compute DF + (S); foreach \underline{n} \in DF + (S) do 

if \underline{t} live-in at \underline{n} then 

Insert a \phi-node for t at n; end 

end end
```

# Renaming the temporaries

```
begin
    foreach t \in Temporaries do count[t] \leftarrow 0; stack[t] \leftarrow empty; stack[t].push(0);
     Call Rename(Entry):
end
Rename(n) begin
    foreach statement I \in n do
         if stack \not\equiv \phi then
              foreach t \in Uses(I) do i \leftarrow stack[t].top; replace use of t with t_i in I;
         foreach t \in Defs(I) do
              i \leftarrow ++count[t]; stack[t].push(i);
              replace def of t with t_i in I;
    foreach s \in SUCC(n) do
         given n is the jth predecessor of s;
         foreach \phi \in s do
              given t is the jth operand of \phi;
              i \leftarrow stack[t].top;
              replace ith operand of \phi with t_i:
    foreach c \in SUCC(n) do Rename(c);
    foreach statement I \in n, t \in Defs(I) do stack[t].pop();
```

# Renaming the temporaries

After  $\phi$ -node insertion, uses of t are either:

original: dominated by the definition that computes *t*.

If not, then  $\exists$  path to the use that avoids any definition, which means separate paths from definitions converge between definition and use, thus inserting another definition.

ie, each use dominated by an evaluation of t or a  $\phi$ -node for t

 $\phi$ : has a corresponding predecessor p, dominated by the definition of t (as before)

Thus, walk dominator tree, replacing each definition and its dominated uses with a new temporary.

Use a stack to hold current name (subscript) for each set of dominated nodes.

Propagate names from each block to corresponding  $\phi$ -node operands of its successors.

# Translating Out of SSA Form

Replace  $\phi$ -nodes with copy statements in predecessors

V.Krishna Nandivada (IIT Madras) CS6013 - Aug 2021 19/33 V.Krishna Nandivada (IIT Madras) CS6013 - Aug 2021 20/

# Issues in translation - critical edge split

Translating out  $\phi$  nodes.

- The compiler inserts copy statements in the predecessors.
- Is it always safe?
- What if the predecessor has more than one successor?

• The lost copy problem:

# Translation - the swap problem

- The definition of  $\phi$  function:
  - When a block executes, all of its  $\phi$  functions execute concurrently before any other statement in the block.
  - ullet All the  $\phi$ -functions simultaneously read their appropriate input parameters and simultaneously redefine their targets.

V.Krishna Nandivada (IIT Madras)

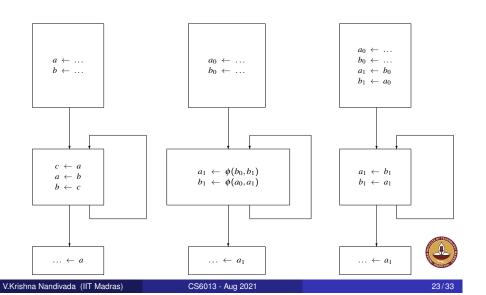

CS6013 - Aug 2021

3-Aug 2021 V.Krishna Nandivada (IIT Madras) CS6013-Aug 2021 CS6013-Aug 2021 And IIT Watrashe. And II

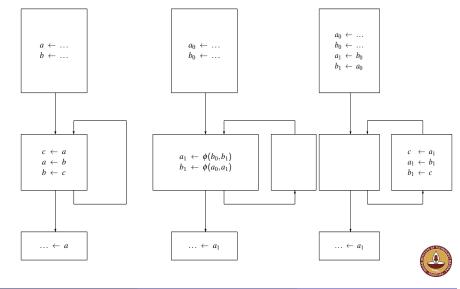

% are not careful and insert the copy statement in the predecessor, we

% lose the copy of 'v' (the old value of 'i')

# (Swap problem) Normal Form, Optimized SSA, **Incorrect Translation**

# Normal Form, Edge-Split Opt SSA, Correct Translation

V.Krishna Nandivada (IIT Madras) CS6013 - Aug 2021

# Translation

- Simply splitting a critical edge does not help.
- One simple way:
  - Step 1: Copy each of the  $\phi$  function arguments to its own temporary name.
  - Step 2: Copy the temps to the appropriate  $\phi$ -function targets.
- Disadvantage: Doubles the number of copy operations.
- Way out Introduce copy only when required.
  - Detect cases in which φ-functions reference the targets of other φ functions in the same block.
  - For each cycle of references introduce copy instructions.

# **Sparse Simple Constants**

- Start with a worklist of all SSA edges.
- Process one edge at a time.
- If the lhs value of an assignment node changes, add all the SSA edges startging from that node to the worklist.

Details: Self reading.

# **Sparse Conditional Constants**

- SSA edge: Data flow (def-use) edges in a program in SSA form.
- Basic idea: Instead of passing all the constants from all the control flow edges, pass constants from SSA edges.
- Resulting analysis faster.

# Sparse Conditional constants

- Works on two worklists:
  - FlowWorkList (contains program flow edges) and
  - SSAWorkList (contains SSA edges).
- Each flow edge has an executable flag tells if the  $\phi$  function at the destination is to be evaluated because of this flow edge initialized to false.

#### Initialization and termination

- Initialize the FlowWorkList to contain the edges exiting the start node of the program.
- The SSAWorkList is initially empty.
- Halt execution when both worklists become empty.
- Execution may proceed by processing items from either worklist.

V.Krishna Nandivada (IIT Madras)

CS6013 - Aug 2021

# Processing SSA edges

- If e is an SSA edge from SSAWorkList then
  - SSAWorkList -= *e*
  - Say  $e = a \rightarrow b$
  - If b is a  $\phi$  node, then Visit- $\phi(b)$
  - Else If b is an expression and if  $\exists c : \mathsf{ExecutableFlag}(c \to b) = \mathsf{true}$ then VisitExpr (Expr(b)); // Note:  $c \rightarrow b$  is a control edge.

# Processing flow edges

- if *e* is a flow edge from FlowWorkList then
  - FlowWorkList -= e
  - if ExecutableFlag(e)=false then
    - ExecutableFlag(e) = true
    - Say  $e = a \rightarrow b$
    - Perform Visit- $\phi$  for all  $\phi$ -nodes at destination node.
    - on the destination node, if only one incoming flow-edges is executable then this this is the first visit to the node
    - If first visit then Perform v = VisitExpr(Expr(b)) destination node
    - if the dest node contains one outgoing CFG-edge then add the edge to FlowWorkList
    - If the dest node contains two outgoing edges then add one / two of them depending on constant value of v.

V.Krishna Nandivada (IIT Madras)

CS6013 - Aug 2021

# Helper function: Visit- $\phi$

- Updates the operands of the  $\phi$  node.
- For each operand  $x_i$  of the  $\phi$  node:
  - ullet set the operand value to oxed if the corresponding program flow edge has ExecutableFlag set to false.
  - Otherwise, replace  $x_i$  with the value of the operand at the definition point.

V.Krishna Nandivada (IIT Madras) CS6013 - Aug 2021 V.Krishna Nandivada (IIT Madras) CS6013 - Aug 2021

# Helper function: VisitExpr (e)

- Evaluate *e* 
  - Normal expressions: using the values of the variables from the definition.
  - $\bullet$   $\phi$  node: take a meet of values of all the operands.
- If the value of the *e* changes:
  - Say, n is the statement node containing e.
  - If *n* is an assignment add to SSAWorkList all the SSA edges starting from *n*.
  - If *n* is a conditional branch: add the newly enabled (because of change in the value of *e*) flow graph edges to the FlowWorkList.

What did we do?

- Static Single Assignment form.
- Sparse Conditional Constant propagation.
