

Rupesh Nasre.

CS3300 Compiler Design IIT Madras Aug 2015

Role

- Read input characters
- Group into words (lexemes)
- Return sequence of tokens
- Sometimes
 - Eat-up whitespace
 - Remove comments
 - Maintain line number information

Token, Pattern, Lexeme

Token	Pattern	Sample lexeme
if	Characters i, f	if
comparison	<= or >= or < or > or == or !=	<=, !=
identifier	letter (letter + digit)*	pi, score, D2
number	Any numeric constant	3.14159, 0, 6.02e23
literal	Anything but ", surrounded by ""	"core dumped"

The following classes cover most or all of the tokens

- One token for each keyword
- Tokens for the operators, individually or in classes
- Token for identifiers
- One or more tokens for constants
- One token each for punctuation symbols

Representing Patterns

- Keywords can be directly represented (break, int).
- And so do punctuation symbols ({, +).
- Others are finite, but too many!
 - Numbers
 - Identifiers
 - They are better represented using a regular expression.
 - [a-z][a-z0-9]*, [0-9]+

Classwork: Regex Recap

- If L is a set of letters (A-Z, a-z) and D is a set of digits (0-9),
 - Find the size of the language LD.
 - Find the size of the language L U D.
 - Find the size of the language L⁴.
- Write regex for real numbers
 - Without eE, without +- in exponent
 - Without eE, with +- in exponent
 - With eE, with -+ in exponent (1.89E-4)

Homework

- Write regex for strings over alphabet {a, b} that start and end with a.
- Strings with third last letter as a.
- Strings with exactly three bs.
- Strings with even length.
- Exercises 3.3.6 from ALSU.

Example Lex

Lex Regex

Expression	Matches	Example
С	Character c	а
/c	Character c literally	*
"S"	String s literally	"**"
	Any character but newline	a.*b
٨	Beginning of a line	^abc
\$	End of a line	abc\$
[s]	Any of the characters in string s	[abc]
[^s]	Any one character not in string s	[^abc]
r*	Zero or more strings matching r	a*
r+	One or more strings matching r	a+
r?	Zero or one r	a?
r{m, n}	Between m and n occurrences of r	a{1,5}
r1r2	An r1 followed by an r2	ab
r1 r2	An r1 or an r2	a b
(r)	Same as r	(a b)
r1/r2	r1 when followed by r2	abc/123

Homework

- Write a lexer to identify special words in a text.
 - Words like stewardesses: only one hand
 - Words like *typewriter*: only one keyboard row
 - Words like skepticisms: alternate hands
- Implement grep using lex with search pattern as alphabetical text (no operators *, ?, ., etc.).

Lexing and Context

- Language design should ensure that lexing can be done without context.
- Your assignments and most languages need context-insensitive lexing.

- "DO 5 I" is an identifier in Fortran, as spaces are allowed in identifiers.
- Thus, first is an assignment, while second is a loop.
- Lexer doesn't know whether to consider the input "DO 5 I" as an identifier or as a part of the loop, until parser informs it based on dot or comma.
- Alternatively, lexer may employ a lookahead.

Lexical Errors

- It is often difficult to report errors or a lexer.
 - fi (a == f(x)) ...
 - A lexer doesn't know the context of fi. Hence it cannot "see" the structure of the sentence – structure is known only to the parser.

- fi = 2; fi(a ==
$$f(x)$$
);

- But some errors a lexer can catch.
 - 23 = @a;
 - if \$x friendof anil ...

What should a lexer do on catching an error?

Error Handling

- Multiple options
 - exit(1);
 - Panic mode recovery: delete enough input to recognize a token
 - Delete one character from the input
 - Insert a missing character into the remaining input
 - Replace a character by another character
 - Transpose two adjacent characters
- In practice, most lexical errors involve a single character.
- Theoretical problem: Find the smallest number of transformations (add, replace, delete) needed to convert the source program into one that consists only of valid lexemes.
 - Too expensive in practice to be worth the effort.

Homework

• Try exercise 3.1.2 from ALSU.

Input Buffering

- "We cannot know we were executing a finite loop until we come out of the loop."
- In C, without reading the next character we cannot determine a binary minus symbol (a-b).
 - ->, -=, --, -e, ...
 - Sometimes we may have to look several characters in future, called *lookahead*.
 - In the fortran example (DO 5 I), the lookahead could be upto dot or comma.
- Reading character-by-character from disk is inefficient. Hence buffering is required.

Input Buffering

- A block of characters is read from disk into a buffer.
- Lexer maintains two pointers: lexemeBegin and forward.

What is the problem with such a scheme?

Input Buffering

- The issue arises when the lookahead is beyond the buffer.
- When you load the buffer, the previous content is overwritten!

Double Buffering

- Uses two (half) buffers.
- Assumes that the lookahead would not be more than the buffer size.

Transition Diagrams

- Step to be taken on each character can be specified as a state transition diagram.
 - Sometimes, action may be associated with a state.

Keywords vs. Identifiers

- Keywords may match identifier pattern
 - Keywords: int, const, break, ...
 - Identifiers: (alpha | _) (alpha | num | _)*
- If unaddressed, may lead to strange errors.
 - Install keywords a priori in the symbol table.
 - Prioritize keywords
- In lex, the rule for a keyword must precede that of the identifier.

Incorrect (lex may	give warning)	Correc	t
"break"	{ return BREAK; }	[a-z_A-Z][a-zA-Z_0-9]*	{ return IDENT; }
[a-z_A-Z][a-zA-Z_0-9]*	{ return IDENT; }	"break"	{ return BREAK; }

Correct

Special vs. General

- In general, a specialized pattern must precede the general pattern (*associativity*).
- Lex also follows maximum substring matching rule (*precedence*).
 - Reordering the rules for < and <= would not affect the functionality.
- Compare with rule specialization in Prolog.
- Classwork: Count number of *he* and *she* in a text.
- **Classwork**: Write lex rules to recognize quoted strings in C.
 - Try to recognize \" inside it.

he and she

What if I want to count all possible substrings *he*? In general, the action associated with a rule may not be easy / modular to duplicate.

Input: he ahe he she she fsfds fsf fs sfhe he she she she

he=5, she=5 he=10, she=5

By the way...

- Sometimes, you need not have a parser at all...
 - You could define *main* in your lex file.
 - Simply call *yylex()* from *main*.
 - Compile using *lex*, then compile *lex.yy.c* using *gcc* and execute *a.out*.

Lookahead

Mud Mud Ke Na Dekh...

Duniya usi ki hai jo aage dekhe

Lookahead

• Lexer needs to look into the future to know where it is presently.

DO 5 I = 1,25

DO / .* COMMA { return DO;}

 / signifies the lookahead symbol. The input is read and matched, but is left unconsumed in the current rule.

Corollary: DO loop index and increment must be on the same line – no arbitrary whitespace allowed.

String Matching

- Lexical analyzer relies heavily on string matching.
- Given a program text T (length n) and a pattern string s (length m), we want to check if s occurs in T.
- A naive algorithm would try all positions of T to check for s (complexity m*n).

- s = ababaa

i = 0 abababaababbbabbabbabbabb ababaa

- s = ababaa

i = 0 abababaababbbabbabbabbabbabbababb

- s = ababaa

i = 1 abababaababbbabbabbabbabbababb ababaa

- s = ababaa

We need to handle the failure better.

- s = ababaa

Key observation: T's current suffix which is a proper prefix in s has the treasure for us. Whenever there is a mismatch, we should utilize this overlap, rather than restarting.

- s = ababaa

Key observation: T's current suffix which is a proper prefix in s has the treasure for us. Whenever there is a mismatch, we should utilize this overlap, rather than restarting.

KMP

- Knuth-Morris-Pratt algorithm for string matching.
- Whenver there is a mismatch, do not restart; rather *fail intelligently*.
- We define a failure function for each position, taking into account the suffix and the prefix.
- Note that the matched part of the large string T is essentially the pattern string s. Thus, failure function can be computed simply using pattern s.

Failure is not final.

Failure function for ababaa

i	1	2	3	4	5	6
f(i)	0	0	1	2	3	1
seen	а	ab	aba	abab	ababa	ababaa

Algorithm given as Figure 3.19 in ALSU.

String matching with failure function

Text = $a_1a_2...a_m$; pattern = $b_1b_2...b_n$ (both indexed from 1)

$$s = 0$$

for (i = 1; i <= m; ++i) { Go over Text
if (s > 0 && a_i != b_{s+1}) s = f(s)
if (a_i == b_{s+1}) ++s
if (s == n) return "yes"
Full match
}
return "no"

Find the flaw in the algorithm.

String matching with failure function

Text = $a_1a_2...a_m$; pattern = $b_1b_2...b_n$ (both indexed from 1)

i	1	2	3	4	5	6
f(i)	0	0	1	2	3	1

Classwork

- Find failure function for pattern ababaa.
- Test it on string abababbaa.

• Fibonacci strings are defined as

$$-s_1 = b, s_2 = a, s_k = s_{k-1}s_{k-2}$$
 for $k > 2$

- e.g., $s_3 = ab$, $s_4 = aba$, $s_5 = abaab$
- Find the failure function for s_6 .

Fibonacci Strings

$$-s_1 = b, s_2 = a, s_k = s_{k-1}s_{k-2}$$
 for $k > 2$

- e.g.,
$$s_3 = ab$$
, $s_4 = aba$, $s_5 = abaab$

- Do not contain *bb* or *aaa*.
- The words end in *ba* and *ab* alternatively.
- Suppressing last two letters creates a palindrome.

• ...

KMP Generalization

- KMP can be used for keyword matching.
- Aho and Corasick generalized KMP to recognize any of a set of keywords in a text.

Transition diagram for keywords he, she, his and hers.

i	1	2	3	4	5	6	7	8	9
f(i)	0	0	0	1	2	0	3	0	3

KMP Generalization

• When in state *i*, the failure function *f(i)* notes the state corresponding to the longest proper suffix that is also a prefix of some keyword.

Transition diagram for keywords *he*, *she*, *his* and *hers*.

i	1	2	3	4	5	6	7	8	9
f(i)	0	0	0	1	2	0	3	0	3

In state 7, character s matches prefix of the keyword she to reach state 3.

Regex to DFA

- Approach 1: Regex → NFA → DFA
- Approach 2: Regex → DFA
 - The ideas would be helpful in parsing too.

Draw an NFA for *.cpp

How does a machine draw an NFA for an arbitrary regular expression such as ((aa)*b(bb)*(aa)*)*?

- For the sake of convenience, let's convert
 *.cpp into *.abb and restrict to alphabet {a, b}.
- Thus, the regex is (a|b)*abb.
- How do we create an NFA for (a|b)*abb?

- For the sake of convenience, let's convert
 *.cpp into *.abb and restrict to alphabet {a, b}.
- Thus, the regex is (a|b)*abb.
- How do we create an NFA for (a|b)*abb?

NFA state	DFA state	а	b

DFA

Regex - DFA

- Regex is (a|b)*abb#.
- Construct a syntax tree for the regex.

Functions from Syntax Tree

- For a syntax tree node n
 - *nullable*(n): true if n represents ϵ .
 - *firstpos*(n): set of positions that correspond to the first symbol of strings in n's subtree.
 - *lastpos*(n): set of positions that correspond to the last symbol of strings in n's subtree.
 - *followpos*(n): set of next possible positions from n for valid strings.

nullable

• Regex is (a|b)*abb**#**.

nullable

Node n	nullable(n)
leaf labeled ϵ	true
leaf with position i	false
or-node n = c1 c2	nullable(c1) or nullable(c2)
cat-node n = c1c2	nullable(c1) and nullable(c2)
star-node n = c*	true

Classwork: Write down the rules for firstpos(n).

firstpos

Node n	firstpos(n)
leaf labeled ϵ	{ }
leaf with position i	{i}
or-node n = c1 c2	firstpos(c1) U firstpos(c2)
cat-node n = c1c2	
star-node n = c*	firstpos(c)

firstpos

Node n	firstpos(n)
leaf labeled ϵ	{ }
leaf with position i	{i}
or-node n = c1 c2	firstpos(c1) U firstpos(c2)
cat-node n = c1c2	if (nullable(c1)) firstpos(c1) U firstpos(c2) else firstpos(c1)
star-node n = c*	firstpos(c)

Classwork: Write down the rules for lastpos(n).

lastpos

Node n	lastpos(n)
leaf labeled c	{ }
leaf with position i	{i}
or-node n = c1 c2	lastpos(c1) U lastpos(c2)
cat-node n = c1c2	if (nullable(c2)) lastpos(c1) U lastpos(c2) else lastpos(c2)
star-node n = c*	lastpos(c)

firstpos lastpos

- followpos(n): set of next possible positions from n for valid strings.
 - If n is a cat-node with child nodes c1 and c2, then for each position in *lastpos(c1)*, all positions in *firstpos(c2) follow*.
 - If n is a star-node, then for each position in *lastpos(n)*, all positions in *firstpos(n) follow*.

If n is a **cat-node** with child nodes c1 and c2, then for each position in *lastpos(c1)*, all positions in *firstpos(c2) follow*.

If n is a **cat-node** with child nodes c1 and c2, then for each position in *lastpos(c1)*, all positions in *firstpos(c2) follow*.

If n is a **star-node**, then for each position in *lastpos(n)*, all positions in *firstpos(n) follow*.

If n is a **star-node**, then for each position in *lastpos(n)*, all positions in *firstpos(n) follow*.

Regex - DFA

- 1.Construct a syntax tree for regex#.
- 2.Compute nullable, firstpos, lastpos, followpos.
- 3.Construct DFA using transition function (next slide).
- 4.Mark *firstpos(root)* as start state.
- 5.Mark states that contain position of # as accepting states.

DFA Transitions

{1,2,3} {6} create unmarked state *firstpos(root*). while there exists unmarked state s { mark s b а a for each input symbol a { uf = U followpos(p) where p is in s labeled a transition[s, a] = uf if uf does not exist unmark uf

Final DFA

DFA

In case you are wondering...

- What to do with this DFA?
 - Recognize strings during lexical analysis.
 - Could be used in utilities such as grep.
 - Could be used in regex libraries as supported in php, python, perl, ... and Vipin's Ruby.
