Realistic modeling and high performance rendering of clothing is a challenging problem. Dynamic cloth simulation software is used for virtual fashion catalogs, as well as for dressing 3D characters for video games, animation movies etc.

Objective:
To develop a cloth simulator using cloth physics, Verlet integration and iterative constraint satisfaction. The simulation of cloth is the simulation of particles with mass and interconnections, called constraints or springs, between the fibers in the cloth. Particles move around in space due to forces that affect them – e.g. wind, gravity, or springs between particles.

Physics:
1. Force can be “translated” into acceleration through Newton's second law: \( \text{acceleration} = \frac{\text{force}}{\text{mass}} \)
2. Acceleration can be “translated” into position by numerical integration – since position \( d(t) \) twice differentiated is equal to acceleration.

Input:
- Wire frame mesh of a rigid structure (e.g simple cases such as Rod, Table, Chair; to complex cases such as human body, sofa etc).
- The cloth parameters and texture.
- Motion dynamics of the supporting object may also be involved.

Output:
Animation & stable position of cloth at the end of a rigid structure.

Process to simulate:
1. Add interaction with wind, collision with ball and enable realistic cloth deformation, wrinkles and movement.
2. Cloth simulation as flag interacting with wind

3. Cloth falling over a rigid rod
4. Hang cloth on string with wind and gravity acting on it. A ball moves horizontally against the hanging cloth.

5. Cloth simulation falling on other rigid structures

Assumption:

-Cloth simulation will be implemented using C++ and openGL.

   - Cloth hanging by 2 points, blowing in the wind, gravity and collision with a ball.
   - OpenGL based cloth simulation code base.
   - Implements all of the existing cloth simulation algorithms
   - Helps beginners and researchers alike to implement the basic algorithms for cloth simulation using OpenGL API.

Currently, this project contains complete implementations of (in alphabetical order)
- Co-Rotated Linear FEM
- Explicit Euler integration
- Explicit Euler integration with texture mapping and lighting
- Explicit Euler integration with wind
- Implicit Explicit (IMEX) method
- Implicit integration (Baraff & Witkin's model)
- Implicit Euler integration
- Meshless FEM
- Position based dynamics
- Semi-Implicit integration (Symplectic Euler)
- Verlet integration
- Verlet integration on CUDA, GLSL (using GPGPU technique) and OpenCL
- WebGL port of Explicit Euler Integration

   - Cloth falling over a ball
