

# Dynamic Analysis

Rupesh Nasre.

CS6843 Program Analysis  
IIT Madras  
July 2025

# Learning Outcomes

- Recall applications of dynamic analysis
- Compare static versus dynamic analysis
- Given a CFG, perform efficient path profiling
- Optimize instrumentation using spanning tree method

# Outline

- Applications of dynamic analysis
  - Limitations of static analysis
  - Trade-offs
- Profiling techniques
- Finding invariants
  - Equality
  - Affine
- Dynamic type inferencing

# Applications

- Bug finding (testing)
- Data race detection
- Identifying security vulnerabilities
- Improved precision of static analysis
- Input-dependent analysis

# Limitations of Static Analysis

- Reduced precision: Over-approximations
- Cannot perform input-dependent analysis

# Static versus Dynamic

- Sound
  - Imprecise
  - Input-oblivious
  - Incomplete
  - Precise
  - Input-dependent
- 
- Choosing between static and dynamic analysis often requires a trade-off between soundness and precision.
  - Current trend is to combine the two techniques to get better precision at improved scalability.

# Profiling

- Profiling is a method of collecting information of interest during program execution.
- The information is often useful to find **hot-spots** in the program.
- Examples
  - Number of times an instruction is executed
  - Number of page faults
  - Number of cache hits
  - Total memory used
  - ...

# Profiling

- **Intrusive**: inserts instructions in the program (source, IR, assembly) **statically**, which get executed at **runtime**
  - File log
  - Memory locations pointed to by a pointer
  - Execution time of a function
- **Non-intrusive**: the program is unaltered; uses external means to profile
  - Hardware counters
  - Program execution time

# Path Profiling

- Consider a program with an entry node and an exit node. There are several execution paths (traces) that the program takes from entry to exit.
- The task is to find the frequency of execution of each path.

Path	Frequency
ACDF	90
ACDEF	60
ABCDF	0
ABCDEF	100
ABDF	20
ABDEF	0

# Path Profiling

- Naïve path profiling is expensive: instrumenting each path may lead to exponential blow up in computation and storage.
- This can lead to unacceptable program slowdown.

# Edge Profiling

- Path profile is approximated as an edge profile
- The frequency of each edge is calculated – which is used to find the path frequency

# Edge Profiling

- Path profile is approximated as an edge profile
- The frequency of each edge is calculated – which is used to find the path frequency

Path	Frequency
ACDF	110
ACDEF	150
ABCDF	100
ABCDEF	100
ABDF	20
ABDEF	20

Choose the minimum edge-frequency in the path

# Path vs. Edge Profiling

- Path profile is approximated as an edge profile
- The frequency of each edge is calculated – which is used to find the path frequency

- Can this instrumentation be optimized?
- Can we have better precision?

Is this a viable profile?

Path	Path Frequency (actual)	Path Frequency (estimated)
ACDF	90	110
ACDEF	60	150
ABCDF	0	100
ABCDEF	100	100
ABDF	20	20
ABDEF	0	20

# Edge Profiling

- Edge profile may not always be a good indicator of a path profile.
- The same profile may refer to different actual path profiles.

Path	Frequency	Actual Freq.	Actual Freq. 2
ACDF	110	90	110
ACDEF	<b>150</b>	<b>60</b>	<b>40</b>
ABCDF	100	0	0
ABCDEF	100	100	100
ABDF	20	20	0
ABDEF	20	0	20

# Efficient Edge Profiling

- Observation: We do not need to instrument every edge.
- How to find a minimal, low-cost set of edges to instrument?
- Use a spanning tree (instrument non-st edges):
  - reduced instrumentation along paths,
  - not all edges carry instrumentation

**Classwork:** Find counts for uninstrumented edges.

Path	Frequency
$C \rightarrow D$	$ac + bc$
$D \rightarrow F$	$ac + bc + bd - de$
$E \rightarrow F$	$de$
$A \rightarrow B$	$bc + bd$
$F \rightarrow A$	$ac + bc + bd$

Needs a unique variable along each instrumented edge.

# Proof of Why Instrumenting non-ST Edges Suffices

- **Vaishnavi's Proof:** For a leaf node in the ST, all but one incoming edge are instrumented. Thus, we can know the non-instrumented edge's count via flow-conservation. This can be repeated for the whole ST.
- **Sahil's Approach:** Writing these flow-conservation equations with ST and non-ST counters gives a set of linear equations. If we can show that the equations can be simplified with only the non-ST counters, that will be a proof. This relates to the rank of the matrix w.r.t. only the non-ST counters.

# Story So Far...

- We want path profile (most precise).
  - But it is expensive to compute and store.
- So we approximated it with edge profile.
  - But that is also inefficient.
- So we performed efficient edge profiling.
  - It is better, but can be improved.
  - Also, what we want is path profile.
- Can we perform efficient path profiling?
  - Apply the learning from edge profiling to develop a technique for efficient path profiling?

# Efficient Path Profiling

- Single index variable across all paths
- Path linearization: Unique (and consecutive) path numbering, which enables indexing
- Most hardware support registers, fast increment and indexing

Check the value of  $x$  for each path.

Path	$x$
ACDF	0
ACDEF	1
ABCD F	2
ABCDEF	3
ABDF	4
ABDEF	5

**Classwork:** Prove that such a path numbering is unique.

# Efficient Path Profiling

- Path numbering is not unique

Path	x
ACDF	0
ACDEF	1
ABCDF	2
ABCDEF	3
ABDF	4
ABDEF	5

In all the above cases, the path numbering is the same, number of instrumented edges (5) is the same

So, which instrumentation should we choose?

# Efficient Path Profiling

1. Assign integer values to edges such that no two paths compute the same path-sum.
2. Use a spanning tree to select edges to instrument and compute the appropriate increment.
3. Select appropriate instrumentation.
4. After collecting the run-time profile, derive the execution paths.

# Efficient Path Profiling

1. Assign integer values to edges such that no two paths compute the same path-sum.
2. Use a spanning tree to select edges to instrument and compute the appropriate increment.
3. Select appropriate instrumentation.
4. After collecting the run-time profile, derive the execution paths.

$\text{NumPaths}(\text{node}) = 0$

$\text{NumPaths}(\text{leaf}) = 1$

In reverse topological order

For each edge  $v \rightarrow w$  {

$\text{Val}(v \rightarrow w) = \text{NumPaths}(v)$

$\text{NumPaths}(v) += \text{NumPaths}(w)$

}

# Efficient Path Profiling

1. Assign integer values to edges such that no two paths compute the same path-sum.
  2. Use a spanning tree to select edges to instrument and compute the appropriate increment.
  3. Select appropriate instrumentation.
  4. After collecting the run-time profile, derive the execution paths.
- Find a spanning tree.
  - Find **chord** (non-ST) edges.
  - For each chord, find fundamental cycle.

# Efficient Path Profiling

1. Assign integer values to edges such that no two paths compute the same path-sum.
2. Use a spanning tree to select edges to instrument and compute the appropriate increment.
3. Select appropriate instrumentation.
4. After collecting the run-time profile, derive the execution paths.

Chord AC: cycle ACDF : 0  
Chord BC: cycle ABCDF : 2  
Chord BD: cycle ABDF : 4  
Chord DE: cycle DEF : 1

# Efficient Path Profiling

1. Assign integer values to edges such that no two paths compute the same path-sum.
2. Use a spanning tree to select edges to instrument and compute the appropriate increment.
3. Select appropriate instrumentation.
4. After collecting the run-time profile, derive the execution paths.

*Prelude:* Allocate and initialize the array of counters

*Postlude:* Write the array to permanent storage

*Main:*

- Initialize path register  $r$  in the entry vertex
- Increment path memory counter in the exit vertex
- Optimizations

# Efficient Path Profiling

1. Assign integer values to edges such that no two paths compute the same path-sum.
2. Use a spanning tree to select edges to instrument and compute the appropriate increment.
3. Select appropriate instrumentation.
4. After collecting the run-time profile, derive the execution paths.

## Path Regeneration

- Path id  $\rightarrow$  Path mapping?
- Traverse the CFG with the number (as the budget) and greedily exhaust the number (e.g., check 3).

Path	id
ACDF	0
ACDEF	1
ABCDF	2
ABCDEF	3
ABDF	4
ABDEF	5

# Classwork

Find the instrumentation for the following CFG such that

- each path receives a unique number
- each path id belongs to  $[0..P-1]$  where  $P$  is the number of paths
